cop. 2

Journal of the Society of Chemical Industry.

INDEX OF VOL. VIII.—1889.

INDEX OF AUTHORS' NAMES.

	PAGE		PAGE
Abakanowicz, B. A., and Arsonval, A. d'. Electric batteries.....	402	Andreoli, E. M. H. Sodium Hypochlorite	865
Abbe. Refractive Index Apparatus.....	614	Bleaching Paper Pulp by Electricity.....	721
Abbot and Trimble. Solid Hydrocarbons in the Vegetable Kingdom	124	Andrews, A. Varnish for Iron.....	291
Abbott. Vulcanising India-rubber.....	376	Andria, M. N. d'. Ammonia Salts.....	284
Abegg, W. A. Quicksilver in Russia.....	657	Purification of Hydrochloric Acid.....	45
Abel, Sir F. A. Gum-cotton.....	518	Treatment of Acid Liquors from Galvanising Works.....	52
Flashing Point of Petroleum.....	734	Treatment of Scrap Tin.....	53
Abel, W. J. Discussion on Technical Education.....	348	Amab, J. Lubricating Compound.....	467
Abell, W. P. Centrifugals for Sugar.....	107	Annaudale, J. H. Paper Manufacture.....	634
Abenius. Piperazine.....	576	Appleton, D. See Hopkinson.....	604
Acheson, E. G. Generation of Electricity by Heat.....	901	Appleyard, J. R. See Knecht.....	457
Acland, T. D. Superphosphates as Manure.....	315	Archbutt, L. Olive Oil.....	685
<i>Action Ges. f. Anil. Fab.</i> Brown Colouring Matters.....	538	Arche, A. Separation of Lead from Silver.....	190
Homologues of Primulines.....	980	Archer, J. B. Gas Manufacture.....	872
Naphthol disulphonic Acid.....	280, 281	Water Oil Gas.....	51
<i>Actienes f. Chem. Ind. Rheinau.</i> Retenequinone Colours.....	279	Archleb, J. Alcoholic Fermentation.....	300
Adair, T. Butter Manufacture.....	409	Aria, C. D. Papier Maché.....	565
Adametz, T. Endosperm of Barley.....	290	Armstrong, H. E. Cinchona Alkaloids.....	160
Adams, P. H. and O. T. X. Treatment of Ores.....	989	Discussion on Technical Education.....	331
Adant, G. Slab Sugar Manufacture.....	810	Naphthol Sulpho Acids.....	277
Addis, Y. H. Mexican Pottery Glaze.....	707	Armstrong and Ackworth. Action of Cupric Nitrate.....	858
Adrian, L. A. Evaporator for Extracts (illus.).....	184	Armstrong and Fielden. Artificial Boracol.....	476
Pharmaceutical Extracts.....	210	Arnaut, M. Strophantus Globre.....	211
Adrian, M. Alcohol and Water Tannins.....	184	Tauhinin.....	1008
Agricola. Manufacture of Steel.....	787	Arnold, D. J., and Coryell, H. B. Dry Galvanic Battery.....	865
Aguiar. Naphthylene diamines.....	278	Arnoux. Anagris betida.....	413
Ahrens, P. B. Mandragora Alkaloids.....	814	Aronstein, L., and Holleman, A. F. Stilbene.....	114
Mandragorin.....	915	Arsonval, A. d'. See Abakanowicz.....	402
Aikman, C. M. Discussion on Technical Education.....	246	Artmann. Creolin.....	274
Aikman, D. Treatment of Pent.....	382	Arzeno. See Cella.....	63
Alberger, J. L. and others. Salt Manufacture (illus.).....	885	Asboth, A. v. Estimation of Starch.....	574
Albert, H., Fellner C., and Ziegler, C. Pyrites Furnace.....	119	Starch Determination.....	428
Alexander, F. H. Secondary Batteries.....	805	Asboth, H. von. Pyridine in Amyl Alcohol.....	734
Alla, L. See Aubin.....	309, 574	Ascough, J. Antiseptic Washing Compound.....	391
Allan, D. See Bishop.....	177	Ashley, E. A. Scouring Soap.....	467
Allan, J. See MacIvor.....	552	Ashley, H. M. Bottle Machine.....	780
Allen. Clarke's Soap Test.....	256	Ashwell, J. R. Discussion on Technical Education.....	317
Allen, A. H. Condenser Support (illus.).....	82	Askew, C. B., and Pumpelly, J. K. Secondary Batteries.....	804
Discussion on Action of Water on Lead.....	251	Assumpção, C. A. d., and Dias, E. T. Treatment of Coal.....	873
Discussion on Borax Lake.....	857	Atherley, R. L., and Sarti, A. E. Gold Extraction.....	804
Paraffin Wax.....	463	Atkins, C. H. Treatment of Paper Pulp (illus.).....	209
Allen, G. W., and Bowers, H. J. A. Purification of Water.....	271	Atkins, G. J. Treatment of Gold Ore.....	200
Allen, H. Effect of Rolling and Drawing on Steel.....	51	Atorburg. Naphthylene diamines.....	278
Allihn, F. Zero Points of Thermometers.....	886	Aubin, E., and Alla, L. Nitrogen Determination.....	309, 574
Alliott, J. See Newlands.....	128	Auer. Chlorate of Potash.....	168
Althausse, M., and Thruss, G. Absorption Spectra of Organic Compounds.....	1012	Auer, H. See Bolton.....	706
Absorption Spectra of Naphthylamine Derivatives.....	367	See Wylie.....	884
Amthor, C. Maltose.....	57	Ange, A. Soda Alum.....	706
Anderson. Cotarnine.....	59	Ange, E. Alumina Salts.....	393
Vulcanised India rubber.....	376	Ausserwinkler, L. Tests for Fats.....	159
Anderson, P. E., and Hodzson, S. Treatment of Wool.....	282	Avenarius, R. Preservative Paint.....	163
Anderson, I. M. T. and A. Explosives.....	818	Averell, J. D. Gas Manufacture.....	534
Andés, L. E. Disinfectant Varnish.....	553	Avery, R. B. Gas Generators.....	272
Andiran, A. J. J. d'. See Durand.....	581		
André. Action of Magnesium Chloride on Lead Oxide.....	794		
Nitric Acid in Plants.....	405		
André, G. Ammonia-Chlorides of Mercury.....	915, 916		
See Berthelot.....	56		
		<i>Edcock and Wilson Company.</i> Bagasse Furnaces.....	910
		Bach. Testing Carbolic Powder.....	1013
		Bach, O. Testing Machine Oils.....	999

	PAGE		PAGE
Bache-Wuz, H. and C., and Drewsen, V. B. Cellulose.....	814	Beechi. Test for Cotton-Seed Oil	63
<i>Badische Anilin- u. Soda Fabrik.</i> Alizarin Black.....	772	Test for Lard.....	644
Colouring Matters	770, 771, 772	Testing Lard	31
Liquid Chlorine (illus.)	777	Beckett, G. H. Production of Ammonia.....	507
Methylene Blue	557	Beckwith, J. H. See Howe.....	35
Naphthalene Dyes (Rosinduline).....	877	Bequerel, E. Phosphorescent Sulphides.....	117
Nitroso-Compounds	280	Bédard, V. See Hervieux, G.....	624
Rhodamines	389	Bedson. Discussion on Technical Education	312
Baessler. Cultivation of Potatoes	205	Bedson, P. P. Aluminium from Cryolite.....	985
Baeyer and Bloem. Dihydroxyquinoline	769	Salt Stalactites.....	98
Baeyer and Fritsch. Sinalbin Derivative	915	Breman, J. S. See Johnson, M.....	713
Baeyer. See Claisen.....	556	Beer, F. Composition for Moulding.....	621
Bailey. Discussion on Calorific Value of Coal	527	Behrend, P. and Kast, H. Titration of Gases.....	136
Discussion on Technical Education.....	398	Beilby. Distillation of Shale	102
Bailey, G. H. Sulphur in Coal	360	Beilby and McArthur. Distillation of Paraffin.....	166
Bailey, M., and Warner, J. Plates for Secondary Batteries...	201	Boilestein and Jawein. Electrolytic Analysis.....	257
Bailey, T. L. Sulphur in Coal.....	361	Boilestein and Kahlberg. Nitronaphthylamine	386
Bailhaeche. Nitric Acid Determination.....	820	Boilestein. Test for Beef Stearin	31
Bairds, Messrs. Ammonia from Blast Furnaces.....	787	Belitzki. Gelatin Emulsion	725
Baker, H. M. Magnesium Chloride	191	Bell, J. F. Water Gas	605
Ball, E. J., and Brough, E. H. Amalgamation of Ores (illus.)	287	Bell, Sir L. Gaseous Fuel.....	761, 863
Ball, E. J., and Wincham, A. Influence of Copper on Steel ..	516	Iron smelting.....	890
Ball, E. J. See Roberts-Austen	808	Iron and Steel Industry	782
Balls, M. Reduction of Tartaric Acid	474	Vote of Thanks to President.....	510
Balp and Broglio. Tertiary Amyl Nitrite	1003	Bell, R. Ammonia from Shale.....	102
Bamberger, E. Fichtelite.....	383	Paraffin Oil.....	100
Bamberger, E., and Bortd, F. Tetrahydronaphthylamine ..	387	Bell, W. Sodium Sulphate in the Fixing Bath	725
Bander, F. Sugar refining.....	128	Bellingrodt, P. Basic Bismuth Nitrate.....	210
Banz. Impurities in Alcohols	324	Bender, F. α -Naphthol Sulphonic Acids	609
Bang and Ruffin. Purification of Spirit (illus.).....	412	Benedikt. Detection of Mineral Oils.....	735
Bannister, J. W. Dyeing Fabrics.....	190	Turkey Red Oil	573
Bannist, M. C. Pumps for Gases	111	Turkey Red	188
Barbe. Vinegar Manufacture	393	Benedikt and Cantor, M. Determination of Glycerol.....	574
Barber-Starkey, W. J. S. Electric Batteries.....	714	Estimation of Glycerol	60
Barbezat and Obregia. Sulphur Determination.....	967	Benedikt, R., and Grussner, A. Analysis of Ethereal Oils ..	925
Barbier, J. Electrical Accumulators	51	Benedikt, R., and Grussner, H. Determination of Methoxyl (illus.)	735
Barlet, G. Exalgine	567	Benedikt, R., and Hazura, K. Composition of Solid Fats.....	897
See Dujardin-Beaumetz.....	412	Benedikt and Zsigmondy. Estimation of Glycerin.....	6
Barker, H. Gluten Manufacture.....	633	Benewitz, C. Potato Spirit.....	559
Barnsiddle, W. Desiccating Blood, &c.....	294	Bennett, J. D. Aluminium.....	800
Barret. Electrical Properties of Silicon Steel.....	796	Benneth. Opal Glass	195
Barth. See Hasiwetz.....	174	Bennard. See De la Roche	32
Barth, L., and Herzig, G. Hermaria.....	815	Bérard, G. H. Treatment of Peat Fibre.....	539
Bartlett, C. H. Balances.....	604	Berend, O. A. Filter (illus.)	379
Bartlett, F. L. Lead Pigments	808	Bergé, A. H. J. Saccharification	633
The Leadville Sulphurets	836	Berger. Naphtholsulphonic Acids.....	384
Treatment of Ores	989	Bergh, W. Centrifugal Separators	530
Bartlett, J. M. See Jordan, W. A.....	629	Bergmann. See Fresenius.....	261
Bass. See Ellenberger.....	113	Berkovits, M. See Reisz.....	802
Batchelor, T. C. See Butterfield.....	1009	Bernard, C. Influence of Carbonic Oxide on Germination....	554
Bateman, F. W. M. Marking Transparent Soap	807	Bernheim. Buetrin in Grain	590
Batho. Steel Furnace.....	546	Bernreuther, K., and Kumpfmiller, W. Maceration of Barley.	301
Baubigny, H. Action of Sulphuretted Hydrogen on Zinc Salts	216	Bernthsen, A. Methylene Blue	152
Separation of Zinc from Nickel	307	Hydrazone of Acridylaldehyde	596
Separation of Zinc and Cobalt	179	Berthelot. Action of Acids on Thiosulphates.....	619
Baubigny, M. Separation of Cobalt and Nickel.....	62	Alexandrin Blue.....	113
Bauer, E. Saccharification of Starch	561	Benzene in Coal Gas.....	221
Bauer, P. T. Coke Ovens.....	10	Combustion.....	181
Bauer, R. W. Sugar from Laminaria	106	Congress of Chemistry.....	656
Bauer, T. von. Coke Ovens	873	Dinitrobenzene.....	283
Baurmeister, A. See Fleiner.....	462	Fixation of Nitrogen by Soil.....	626
Baum. See Schaffer.....	609	Gas Analysis	64
Baumann, A. Weight of N ₂ O, per cent. of NO	125	Heat developed by Solution of Hydrochloric Acid Gas in Water.....	861
Baumann and Gersons. Guanidine	131	Nitric Acid in Plants.....	405
Baumann. Boric Acid in Plants	569	Raffinose.....	993
Baumann, G. Boric Acid in Vines.....	130	The Thionine Series.....	541
Baumann, A. Refining Sugar	510	Berthelot and André, G. Nitrogen in Soils.....	56
Baur, A. Musk Substitute	1004	Berthelot. Prussian Blue	758
Baxter, R. S., and MacDonald, G. D. Cotton Seed Cake.....	631	Bertoni. Amylo-nitrous Ether	1003
Bayer. Croceine Sulphonic Acid	276	Bertram, A. N. Treatment of Noxious Fumes.....	814
Bayer, F. & Co. Blue Azo-Dyes	41	Bertram, J., and Gildemeister, E. Betel Oil	816
Printing Azo-Colours	12	Bertschinger, A. Sand Filters at Zurich	998
Bayley and Lomas. Titration of Webbon Mud.....	968	Berzelius. Action of Sulphuretted Hydrogen on Zinc Salts	216
Baynes, J., and others. Composition for Ships' Bottoms.....	808	Lamp	61
Bazin, E. Production of Cold	759	Selenium.....	658
Beach, W. H. Receiver for Volatile Liquids	1009	Sulphuric Acid Process.....	105
Beau, W. See Lefmann, H.....	480, 561	Bessemer, H. Malleable Iron	787
Beau, E. Insecticide.....	111	Besson. Cupokt.....	395
Beardmore, T. Valves for Regenerative Furnaces.....	767	Beswick, S. E. Varnish for Harness.....	716
Beardsley, M. W. See Pearce.....	174	Bevan, E. J. Discussion on Applications of Oxygen	86
Beauffy, M. H., and Cartwright, J. Non-Alcoholic Beverage ..	295	See Cross.....	5, 252
Beaumont, E. A. B. Treatment of Beer, &c.....	995	Beveridge, J. Smoke-consuming Furnace.....	39
Beaurepaire, M. Durane.....	187	Bewlay, H. See Lloyd, G. H.....	767
Bechamp, A. Milk.....	58	Beythien, A., and Tollens, B. Raffinates.....	557
		Bibbins, T. L. See Wilson, R. P.....	465
		Biehler, J. See Reisz.....	802

	PAGE		PAGE
Bichon, Cupola.....	395	Boussingault, Nitric Acid in Rain.....	627
Bickford, Fuse.....	417	Oxygen.....	82
Bickford and Co. Fuse Igniter.....	818	Bowen, E. Tin Plate Liquors.....	193
Bidet, A. Influence of Thiophen on Benzene Derivatives.....	383	Bowen, O., Tomkins, A. S., and Cobdellick, J. Charcoal Manu- facture.....	61
Biedermann, E., and Harvey, E. W. Regenerative Furnace.....	765	Bower, H. Facilitating Chemical Reactions.....	972
Billault, E. A. Coating Metals with Sulphide of Silver.....	188	Bowers, H. J. A. See Allen.....	271
Billings, P. See Letalle, A. E.....	477	Bowick, Purification of Spirit (illus.).....	443
Binder, P. See Noetting, E.....	188	Bowley, J. J. Soap.....	714
Binnis, F. J., and Paris, R. J. Composition for Ships' Bottoms.....	291	Bowman, Discussion on Technical Education.....	347
Bison and Grandtits, Zinc extraction.....	545	Bowman, F. H. Structure of Wool.....	18
Birhans, F. Solid Nitrogen Trioxide.....	726	Bowman, R. D. Mantles for Incandescent Lamps.....	973
Birrell, H. A. Treatment of Ground Malt.....	966	Bowry, Urechitine.....	111
Bischof, G. Discussion on Explosives.....	524	Box, Dissipation of Heat.....	855
Bischoff, C. A. Piperazines and Hydrated Diazines.....	976	Boyer, S. S., and Steele, P. P. Treatment of Fibre.....	303
Quinoline Derivatives.....	769	Boyd, W. See Campbell, A.....	534, 703, 983
Bischoff, C. A., and Nastvogel, O. Acipiperazines.....	977, 978	Boyon, E. von. Higher Aromatic Hydrocarbons.....	974
Bishop, G. T. Soap Manufacture.....	991	Residual Paraffin.....	273
Bishop, F., and Allan, D. Washing Photographs.....	477	Bradburn, J. A. Caustic Soda.....	797
Bishop and Engé, L. Cotton-Seed Oil in Lard.....	63	Bradford, Separation of Zinc and Manganese.....	62
Black, W., and Remoldson, W. L. Antiseptic.....	131	Bramhall, Cupola.....	393
Blackmore, H. S. Sodium Manufacture.....	122	Branwell and Hughes, Cyanogen.....	758
Blair, A. A. Analysis of Iron.....	496	Brand, A. Electrolytic Separation of Metals.....	1011
Blair, F. A. Dye Vats, &c.....	982	Brandenburg, P. Pure Grape Sugar.....	470
Blakely, W. Funnels.....	808	Brands, W. Creosote.....	422
Blancaneaux, H. B. de. Cutter for India-rubber Trees.....	808	Branson, F. W. Triple Bunsen Burner (illus.).....	957
Blass, E. See Fox, S.....	873	Brasier, E. Fibrous Sheets or Slabs.....	513
Blenkinsop, W. E. H., and Lyte, F. M. Lead Salts.....	777	Treatment of Fibres.....	634
Blechnmann, The Bunsen Lamp.....	180	Braylants, Influence of Saccharine on Digestion.....	813
Blöem, See Baeyer.....	769	Brazier, E., and Thompson, J. Tin-plating.....	801
Blomstrand, Swedish Copper Mines.....	658	Breden, A. See Koffler.....	400
Bloxam, Sodium Flumo.....	179	Bredig, See Will.....	59
Blum, L. Carbon in Iron.....	922	Bredt, P. Slag as a Manure.....	125
Magnesia Determination.....	922	Brein, F. Solubility of Wool.....	458
Manganese Determination.....	922	Triphenylpararosaniline.....	455
Sulphur in Coal.....	361	Turkey-red Oil.....	573
Blumenthal, See Randohr.....	191	Brenner, G. N. Treatment of Sewage.....	411
Boa, Discussion on the Work of the Sections.....	969	Brémont, Desiccation of Gas.....	949
Boake, A., and Roberts, G. A. Treatment of Paper Pulp.....	565	Brentini, P. Removing Paint.....	716
Boake, A., and others, Sodium Meta-sulphite.....	119	Brevort, H. L. See Roberts, J. L.....	623
Boas Bonsson, See Nötting.....	422	Breyer, J. Raffinose in Raw Sugar.....	616
Bobrownicki, A. Treatment of Refuse.....	1090	Breze, J. H. Condensers.....	271
Boeard, Cupola Blast.....	391	Briem, H. Sugar Beet.....	628
Boek, J. Sugar Candy.....	632	Brighthouse, G. See Davies.....	269
Boddé, H. Distinction of Resorcinol.....	734	Brin, A. Oxygen Manufacture.....	46, 411
Bode, F. Lead for Vitriol Chambers.....	774	Oxygen.....	694
Specific Heat of Sulphuric Acid.....	543	Brin, L. Q. Aluminium Alloy and Plating.....	199
Boehm, See Engler.....	106	Aluminium Bronze.....	339
Boehring, Eseridine.....	1061	Aluminium Plating, &c.....	548
Boessneck, P. Valuation of Argol.....	420	Aluminium Plating.....	897
Bohlig and Hoyne, Magnesium Chloride.....	191	Iron Alloys.....	897
Böhlin, Curarine.....	476	Brin's Oxygen Company, Aeration of Liquids.....	759
Bohm, W. D. Expulsion of Gases from Solutions.....	399	Ageing Wines, &c.....	812
Filtration (illus.).....	271	Purification of Gas.....	381
Bohme, Cement.....	782	Visit to Works of.....	517
Influence of Frost on Cement.....	393	Brin's Oxygen Company and Goble, P. B. W. Carbonated Oxygen Water.....	301
Magnesia in Cements.....	59	Brisset, M. V. Purification of Fats.....	624
Silver Gray Dye.....	981	Bristol, L. Electrical Accumulators.....	623
Böhringer u. Sohn, Cocaine.....	1004	Britton, J. B. Chromium Determination.....	421
Bolley, Allotropic Lead.....	52	Brocklehurst, G. Evaporating Pans.....	107
Bolton, Micro-organisms in Water.....	911	Broglio, See Balp.....	1003
Bolton, G. H., and Bullough, T. A. Treatment of Lime Mud.....	779	Bromeis, Fichtelite.....	582
Bolton, G. H., and others, Permanganates and Chlorates.....	706	Brönner, β -Naphthylaminesulphonic Acid.....	699
Bolton, G. H., and Wyde, J. R. Multiple Effect Evaporation.....	884	Naphthol Sulpho Acids.....	276
Bombelon, E. Mercuro- β -Naphthol.....	1093	Brook, E. Gas Producers.....	581
Mercury- β -Naphthol Acetate.....	596	Brook, E., and Wilson, A. Gas Producer.....	533
Bondonneau, M., and Foré, G. Sugar from Starch.....	295	Brook, R. G. See Johnson, J.....	539
Boniza and Negrita, Lantamine.....	477	Brooke, Simpson, and Spiller, Primuline.....	389
Bonnard, J. B. G. Decoration of Glass, &c.....	196	Brotherhood, C. Oil Gas.....	873
Photographing in Colours.....	414	Brough, B. H. See Ball.....	287
Bonne, C. R. Treatment of Brewers' Worts.....	812	Brown, A. P. Mercury Oleate.....	567
See St. George.....	54	Brown, H. T., and Morris, G. H. Molecular Weights of the Carbohydrates.....	717
Borbély, Puddling Furnace.....	894	Amylodextrin.....	746
Bordt, F. See Bamberger.....	387	Brown, J. Campbell, Discussion on Technical Education.....	357
Borgmann, E., and Fresenius, W. Pure Sherry Wines.....	56	Report on Technical Education.....	359
Borland and Reid, Carbo-dynamite.....	522	Discussion on Electrolytic Analysis.....	262
Börnstein, E. Detection of Saccharin.....	216	Discussion on Chlorate of Potash.....	172
Borntrager, H. Examination of Spirit.....	64	Brown, W. Dyeing, Scouring, &c.....	704

INDEX OF SUBJECTS.

	PAGE		PAGE
Absorbent Surfaces, Porous	393	Alkalis from Slag	399
Absorber for Gases	449	Sodium Nitroprusside as Test for	920
Acacia (Australian Wattle)	903	Alkaloids, Reactions of	421
Accumulators	401, 402	Alloys	36, 120, 199, 200, 399, 549, 712, 713
Electrical	54, 201, 289, 405, 623, 624	Aluminium	464
Theory of Lead	899	Allyltribromide	413
Acenaphthene Perhydride	451	Almond Water, Bitter	567
Acetal in Spirit	64	Alpha-naphtholdisulpho Colours	770
Acetamide, Detection of	63	Alum, Soda	706
Reaction	307	Alumina Lustres	984
Acetic Acid Manufacture	543, 697	Salts	393
Rectification of	777, 779	Titration of	252
Acetone on Amidophenols, Action of	384	Aluminium	463
Acetone Manufacture (illus.)	1008	Alloys (illus.)	199, 548, 549, 677, 713
Estimation of	138	Bronze	399
Acetylisoavanillic Acid	816	Chloride	283
Acetylphenylglycine	978	Chloride Manufacture	706
Acetylphenylhydrazine	476	Deposited on Iron	199
Acid Production in France	228	Determination in Iron	965
Pump	380	Extraction	288, 547, 548, 549, 989
Tars, Treatment of	112	And Iron, Separation of	260
Acids, Affinities of Organic	1012	Manufacture	122, 198, 800, 985
Acids and Bases, Interdiffusion of	775	Plating	548, 551, 897
Acids, &c., Evaporation of	780	Separation of	804
Acipiperazines	977, 978	Sulphate, Free Acid in	479
Aerose from Formaldehyde	206	Triple Alloy	897
Address at Annual Meeting, President's	505	United States, Product of	590
Adonidin	1003	Aluminous Cake	720
Aération of Materials	111	Amalgamation of Ores	200, 547
Aerated Waters, Acid for	706	Amalgamation Process (illus.)	287
Affinity Values of Organic Acids and Bases	1012	Amalgams	713
Asaric Acid	413	Amaranth	389
Asiculture in Canada	483	Amber, Optical Properties of	291
Agricultural Experiments, the Rothamsted	820	American Trade, A Century of	430
Air Bath for Small Retorts (illus.)	134	Amido-Acids, G. and R.	277
Air, Carburetted	272	Amidoazobenzene Derivatives	878
Freed from Germs	472	Amidobenzophenones, Rosanilines from	536
Micro-Organisms in the	911	Amidobenzylsulpho-Acid	611
Pyrometers (illus.)	214	Amidodimethylaniline Derivatives	453
Supply to Furnaces, Moist	381	Amido-diethylmercaptide	454
Zymotechnical Analysis of	472	Amidonaphthalenesulphonic Acids	116
Alcohol, Aldehyde in	219	Amidoparacresylmethyl Ether	452
From Bananas and Tamarinds	130	Amidophenols	538
From Crude Spirit	812	Action of Acetone on	384
Detection of Impurities in	924	Amido-saccharine	476
Drawback in Germany	1019	Amidotrimethylchlorinol	455
French Statistics of	827	Amidotriphenylmethanes	455
Fusel Oil in	309	Ammonia, Anhydrous Liquid	462
Manufacture	309	Carbonates	292, 779
Purification of	57, 559, 562, 719, 905, 996	From Coke Ovens	382, 697
Purification by Hydrocarbons (illus.)	441	Determination (illus.)	921
Question in Spain	585	Engines	531
Rectification	910	From Impurities in Black Ash (illus.)	351
Russian Export of	483	Manufacture (illus.)	284, 505
For Scientific Purposes in the United States	485	From Molasses	128
Alcoholic Liquors, Medicinal	995	Nitrate Manufacture	706
Albumen, Relation of Gelatin to	168	Soda Process Mud, Cement from	820
Albuminoids in Plants	628	Soda Process (illus.)	11, 45
Aldehyde in Alcohol, Determination of	219	Soda Process, History of	460
Blue	384	Solutions, Specific Gravity of	390, 541
In Spirit	64	Standard Solutions	820
Aldehydes, Colour Reactions with	1012	Still (illus.)	103, 884
In Spirit	569	Sulphate, Prices and Statistics	66, 67
Algerian Soils	205	Sulphate Production	665
Alizarin Black	42	Ammoniacal Detergents	403
Blue Derivatives	770, 772	Liquor, Treatment of	193, 402, 534
Green	771, 772	Ammonia, Duty on	1017
Alkali Liquors, Treatment of	884	Ammonium Bromide	210, 636
Mud Cement from	778	Chloride, Action of Calcium Carbonate on	461
In Soap, Caustic	478	Salts in Carnallite	283
In Soap, Free	423	Sulphate, Manurial Value of	810
And Sulphur Process	11	Amyl Alcohol, Injurious Effects of	560
Waste, Treatment of	118, 119	Pyridine in	734
Works, Report on	664	In Spirit	64
Alkaline Nitrites	983	Amyl Nitrite, Tertiary	1003
		Amylenhydrate	1002
		Amylodextrin	716, 717

	PAGE		PAGE
Amyrin	635	Balloon "La France," Electric Battery for	53
Anagyrine	413	Bananas, Alcohol from	430
Analysis, Capillary	569	Bandages, Absorbent	1001
Electrolytic (illus.)	256	Barley of 1888	298
Anemouin	1002	Bohemian	293
Anhydro-ecgonine, Pyridine from	634	Endosperm of	290
Anilidobutyric Acid	978	Maceration of	301
Aniline Black Dyeing	703	Manurial Experiments with	556
Blue Process, Theory of	187	Barytes Pigments	592
Determination	422	United States Product of	590
Non-basic By-products of	386	Bases and Acids, Interdiffusion of	775
Animi Resin, South American	141	Bases, Affinities of Organic	1012
Anisic Acid	566	Bassia Latifolia Juice	124
Annealing Metals	898	Batteries, Bichromate	803
Anodes, Disintegration of	288	Electrical	288, 289, 406
Anthelmintic	1004	Galvanic	54, 623, 714, 803, 804, 805
Anthraquinone Derivatives	112	Galvanic and Secondary	401, 402, 403
Antiegyptian Powder, Italian Duty on	482	Galvanic or Voltaic	123
Antifebrin	63	Secondary	201, 623, 624, 803, 804, 805, 901, 902
Anti-fouling Compound for Iron, &c.	168	Secondary or Storage	280
Anti-inecrustator for Steam Boilers	745	Theory of Secondary	899
Antimony Coating on Iron	406	Utilisation of Waste from	123
Detection of	215	Battery, Electric, for Balloon	53
Determination	1012	Gas (illus.)	509, 550, 990
Electrolytic Determination of	258	Liquors, Treatment of	201
Fluorides	612	Solution, Galvanic	992
Ore, Concentration of	390	Beating Yarns, &c.	189
And Potassium Oxalate	189	Beef Stearin in Lard	30
Salts in Cotton Dyeing	188	Beer	50
Separation of Copper from	733	Clarification of	472
And Tin, Separation of	157	Pasteurisation of	301, 719
Antipyrine, Import Notice regarding (Netherlands) ..	221	Sulphurous Acid in	995
Swiss Duty on	141	Wort, Treatment of	206
Antiseptine	722	Beet. See Sugar Beet	205, 206
Antiseptic	131, 411, 634, 720, 1000, 1001	Beet Analysis	1013, 1014
Paper for Wounds	200	Plant, Formation of Constituents	631
Soap	123, 714, 715	Beetroot, Abnormal	557
Solution	301	Ash	204

Siebenhütten, Gold Mines of the	286	Estimation of Nitrates in	572
Silica, Reduction by Magnesium	622	Non-growing	126
Silicium Copper	898	Influence of Gypsum on	909
Silicon	285	Lime Determination in	735
Determination in Cryolite	572	Nitrates in	306, 420
Determination in Ferro-Silicon	639	Nitrogen in	907, 909
And Iron Alloys	788	Nitrogen Determination	56
Silk, Artificial (illus.)	539, 611	Surface Waters of	907
Assay (illus.)	687	Solanaceae, Alkaloids of the	1002
Determination	923, 1011	Solanine	816
Dry Assay of	137	Solanidine	477
Extraction of	286, 287	Solanine	477
Extraction	197, 198, 199	Soldering	711
Mine in Japan	828	Tin	802
Nitrate, Reactions of Oils with	924	Solubility of Salts	883
Ores, Treatment of	120, 400, 711, 713	Solutions, Constitution of	43
Separated from Lead	990	Gases Expelled from	390
Sulphide applied to Jewellery	988	Sorbinose	206
Ultramarine	713	Sorbite	295, 296
Silvering	987	Hexyliodide from	558
On Glass	196	South Carolina, Phosphate Industry of	143
Sinabin	915	Spain, Trade with	72
Sinapin	915	Spanish Trade with the United Kingdom	316, 589, 826
Sisal Hemp Trade	659	Specific Gravity of Ammonia Solutions	390, 541
Treatment of	611	Gravity Bulbs (illus.)	310
Skein Dyeing	283	Heat of Sulphuric Acid	543
Skins, &c., Treatment of	124, 553, 954	Spectra of Organic Compounds	1012
Slag, Alkalis from	399	Spent Oxide, Treatment of Gas	881
Basic as Manure	557	Spiegeleisen Manufacture	141
Cement	888	Spirit, Annual Production of	472
Desulphurised	623	Denatured	471
Fertiliser	909	Duty-free	300
Highly Phosphoric	549	Examination of	64
Manurial Value of	125, 138	Impurities in	309
Separation of Metals from	201	Manufacture	471, 559, 560
Stone from Basic	544	Purification of	472
Utilisation of	622	Spirits, Distillation of	812
Slags, Analyses of	904	Exported as Medicines, Drawback on	70
Fusing Point of	987	Matured by Means of Oxygen	84
Slate, &c., Decoration of	621	Etc. Maturing	812
Smelting	987, 989	Methylated	70
Smoke	450	Spirituous Preparations, Drawback on	226
Condensation of Carbon in	377	Spray Dyeing Fabrics, &c.	703
Smut in Oats prevented	469	Stand for Laboratory Use	425
Smyrna Chemical Industry	141	Starch Determination	295, 574
Soap	123, 290, 624, 714, 715	Iodide	295
Ammoniacal	403	Manufacture	127, 298, 470, 633, 909
Caustic Alkali in	478	Nitrated	878
Examination of	423	Removed from Cotton	539
Laundry	203	Saccharification of	633
Lyes, Determination of Glycerin in	4	Soluble	716, 717
Manufacture	467, 991	Stassfurt Salts, Production of	314
Markine Transparent	807	Steam Boilers, Anti-incrustator for	715
Meal	552	Purification of Water for	604
Mineral Oil in	991	Condensation of	864
Powder	625, 807	Superheated	379
		Stearic Acid from Oleic Acid	466
		Stearine from Yorkshire Grease	92
		Steatins	641

LIST OF MEMBERS.

A

Abbott, John, Braemar House, Lancaster Gate, Hyde Park, W.
 Abel, Sir F. A., Royal Arsenal, Woolwich, London, S.E.
 Abraham, A. C., Stanley Rock, St. George's Mount, New Brighton (Journals); and 87, Bold Street, Liverpool.
 Acland, Sir H. W., Radclyffe Library, Oxford.
 Adam, A. Learmouth, 40, Sir Michael Street, Greenock, N.B.
 Adam, J. B., 172, Leith Walk, Edinburgh.
 Adams, M. A., Ashford Road, Maidstone, Kent.
 Adams, J. W., 74, Oxford Street, Regent Road, Salford, Manchester.
 Adamson, G. P., Easton, Pa., U.S.A.
 Addie, J., Langloan Ironworks, Coatbridge, N.B.
 Adkins, H., Chemical Works, Smethwick.
 Adriance, John S., 1, East 55th Street, New York, U.S.A.
 Afleck, J., Mill House, Woolton, near Liverpool.
 Aikman, Charles M., 183, St. Vincent Street, Glasgow.
 Aikman, Thomson, jun., 5, Prince's Square, Glasgow.
 Aitken, Dr. A. P., 8, Clyde Street, Edinburgh.
 Aitken, J. B., Gerard's Fold Chemical Works, Widnes.
 Akitt, Thomas, 3, Victoria Road, Lenzie, N.B.
 Albright, G. S., The Elms, Park Road, Edgbaston.
 Albright, W. A., Mariemont, Birmingham.
 Albright, W. B., c/o Halstead & Co., 196-202, Forsyth Street, New York, U.S.A.
 Alexander, J. O., Plantation Leonora, Demerara, British Guiana.
 Alexander, W. T., 20, Booth Street, Moseley Street, Manchester; and Crummock Bank, Victoria Crescent, Eccles.
 Allan, Jno., 12, Woollaston Road, Harringay, N.
 Aldred, C. H., 35, Crisp Terrace, Upper Park Road, Plumstead Common, Kent.
 Allen, A. H., Sydenham Cottage, Park Lane, Sheffield.
 Allen, G. J., Belthles Strasse 47, Tübingen, Germany.
 Allen, J., 164, Upper North Street, Poplar, London, E.
 Allen, Walter S., 13, Beacon St., Boston, Mass., U.S.A.
 Allen, Wm., Edenholme, Bournemouth, Hants.
 Allen, W. H., Peninsular Laboratory, Detroit, Mich., U.S.A.
 Allender, G. M., Stammerham, Horsham, Sussex.
 Allhusen, A., Gateshead-on-Tyne.
 Allhusen, Wilton, 102, Quay Side, Newcastle-on-Tyne.
 Allibon, G. H., Seaview, Litherland Park, near Liverpool.
 Alliott, J., Bingham, Messrs. Manlove, Fryer, Alliott, and Co., Nottingham.
 Alsberg, M. (Sondheim, Alsberg, & Co.), P.O. Box 2437, New York, U.S.A.
 Anderson, Geo. B., Victoria Square, Felling-on-Tyne.
 Anderson, John, Workington Ironworks, Workington, Cumberland.

Anderson, J. M. T., Explosives Co. Ltd., Stowmarket, Suffolk.
 Anderton, G. H., Howendyke, Howden, Yorks.
 Andrew, W. B., Gavinburn, Old Kilpatrick, Dumbartonshire.
 Angell, J., 81, Dueie Grove, Oxford Street, Manchester.
 Angus, James, Thorncliffe Collieries, Chapeltown, Sheffield.
 Angus, John, 3, Brabant Court, Philpot Lane, London, E.C.
 Angus, W. Mathwin, St. John's Leather Works, Newcastle-on-Tyne.
 Annandale, J. H., Polton, Midlothian, N.B.
 Annon, R. H., 16, Water Lane, Tower Street, London, E.C.
 Ansdell, G., 45, Courtfield Road, South Kensington, S.W.
 Ansdell, T. C., Kearsley Cottage, Farnworth, Bolton.
 Archbold, Dr. George, Laboratory, Phoenix, Oswego Co., N.Y., U.S.A.
 Archbutt, L., Argyle Terrace, Rose Hill, Derby.
 Arding, Francis, 5, Jeffreys Square, St. Mary Axe, London, E.C.
 Armstrong, Dr. H. E., Central Institution, Exhibition Road, London, S.W.
 Armstrong, Rt. Hon. Lord, Newcastle-upon-Tyne.
 Ash, T. E., 4, Saltram Place, Citadel Road, Plymouth.
 Ashburn, Wm., 14, Westwood Street, Moss Side, Manchester.
 Ashwell, H., Woodthorpe Grange, Sherwood, Nottingham.
 Ashwell, J. H., Woodthorpe Grange, Sherwood, Nottingham.
 Ashwell, Jno. R., 111, Waterloo Crescent, Nottingham.
 Ashworth L., The Barlows, Radcliffe, near Manchester.
 Atcherley, Dr. R. J., 80, Elsham Road, Kensington, W. (for Journals); and 23, Bucklersbury, E.C.
 Atkins, S. R., Market Place, Salisbury.
 Atkinson, A. J., 44, Loudoun Square, Cardiff.
 Atkinson, R. W., 44, Loudoun Square, Cardiff.
 Attfield, Dr. J., Ashlands, Watford, Hertfordshire.
 Aubrey, W. H., 19, Ryecroft Road, Courthill, Lewisham, S.E.
 Auer, H., Appleton Lodge, near Widnes.
 Auerbach, Dr. C. G., 8, Alderstrasse, Elberfeld, Germany.
 Austen, Peter T., New Brunswick, N.J., U.S.A.
 Austin, E., 126, Bermondsey Street, London, S.E.

B

Babington, F. W., School of Practical Science, Toronto, Canada.
 Bailey, Edwin M., Laboratory, Pumpherson Oil Co., Ltd., Midcalders, N.B.
 Bailey, Wm., The Terrace, Oaken, near Wolverhampton.
 Bailey, Dr. G. H., Owens College, Manchester.
 Bailey, Thos., 25, High Street, Hull.

- Bailey, Richard D., City Brewery, Gloucester.
 Bailey, Dr. T. L., University College, Brownlow Street, Liverpool.
 Bailey, W. H., Albion Works, Salford, Manchester.
 Bailey, Walter P., British Alizarin Works Co., Silvertown, E.
 Bainbridge, Herbert A., Malvern Hall, Solihull, near Birmingham.
 Baker, E., Stoneleigh, Eastern Avenue, Reading, Berks.
 Baker, Harry, The Laurels, Tifford Road, Oldbury, Birmingham.
 Baker, John T., Easton, Pa., U.S.A.
 Baker, W. G., Garden Wharf, Church Road, Battersea, London, S.W.
 Baker, Theodore, E. C. Powder Co., Green Street Green, Dartford, Kent.
 Bald, J. H., Braddock, Pa., U.S.A.

THE JOURNAL OF THE Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 1.—Vol. VIII.]

JANUARY 31, 1889.

[Non-Members 30/- per annum; Members
21/- per Set; Single Copies 2 6.]

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.

COUNCIL FOR YEAR ENDING JULY, 1889.

President: Ludwig Mond.

Vice-Presidents:

Sir I. Lowthian Bell, F.R.S.	David Howard.
R. Forbes Carpenter.	Ivan Levinstein.
Prof. F. Clowes, D.Sc.	E. K. Muspratt.
Sir J. Neilson Cuthbertson.	Sir H. E. Roscoe, M.P., F.R.S.
Prof. James Dewar, F.R.S.	Prof. W. A. Tilden, F.R.S.
Dr. John Evans, F.R.S.	John Williamson.

Ordinary Members of Council:

Alexander M. Chace.	F. J. Rowan.
James Duncan.	Dr. Edward Schunck, F.R.S.
A. E. Fletcher.	E. C. C. Stanford.
S. H. Johnson.	J. C. Stevenson, M.P.
B. E. R. Newlands.	T. W. Stuart.
B. S. Proctor.	Thos. Tyrer.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. Ferdinand Hurter.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

Sir F. A. Abel, F.R.S.	Prof. A. K. Huntington.
A. H. Allen.	F. Hurter, Ph.D.
Prof. H. E. Armstrong, F.R.S.	F. Jones, F.R.S.E.
G. H. Bailey, D.Sc., Ph.D.	Ivan Levinstein.
Joseph Bernays, M.I.C.E.	Prof. R. Meldola, F.R.S.
H. Brunner.	E. K. Muspratt.
W. Lant Carpenter.	C. O'Sullivan, F.R.S.
Prof. Frank Clowes, D.Sc.	John Pattinson.
W. Y. Dent.	W. H. Perkin, Ph.D., F.R.S.
Prof. Jas. Dewar, F.R.S.	Sir H. E. Roscoe, M.P., F.R.S.
John Heron.	John Spiller.
D. B. Hewitt, M.D.	A. Norman Tate.
David Howard.	Thomas Tyrer.
Prof. J. J. Hummel.	

Editor:

Walson Smith, The Owens College, Manchester.

ASSISTED BY THE FOLLOWING STAFF OF

Abstractors:

T. L. Bailey, Ph.D.	W. E. Kay.
G. H. Beckett.	A. J. King, B.Sc.
D. Bendix.	P. S. Kipping, D.Sc.
E. Bentz.	Chas. A. Kohn, Ph.D.
E. E. Berry.	F. W. T. Krohn.
E. J. Bevan.	T. A. Lawson, Ph.D.
Bertram Blount.	J. Walter Leather, Ph.D.
Arthur G. Bloxam.	A. Liebmann, Ph.D.
C. H. Bothamley.	D. A. Louis.
E. G. Clayton.	W. Maenab.
Julius B. Cohen, Ph.D.	G. Harris Morris, Ph.D.
C. F. Cross.	J. M. H. Munro, D.Sc.
A. R. Davis.	H. T. Pentemann.
W. W. Haldane Gee, B.Sc.	S. G. Rawson, B.Sc.
C. Napier Hake.	A. Rec, Ph.D.
S. Hamburger, Ph.D.	F. W. Renaut.
Oswald Hamilton.	A. Studer, Ph.D.
John Heron.	Bertram Thomas.
Bertram Hunt.	Eustace Thomas.
C. C. Hutchinson.	V. H. Velez, M.A.
D. E. Jones, B.Sc.	R. Lloyd Whiteley.
	A. Wingham.

NOTICES.

Members who require back numbers are requested to make application only to the General Secretary.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

Notice is hereby given, for the information of subscribers for this Journal, that Messrs. EYRE and SPOTTISWOODE, Her Majesty's Printing Office, East Harding Street, London, E.C., have been appointed sole agents for the supply of the Journal to non-members and the trade.

LIST OF MEMBERS ELECTED, 23rd JANUARY, 1889.

- Ashburn, Wm., 11, Westwood Street, Moss Side, Manchester, agent.
 Bailey, Richard D., City Brewery, Gloucester, brewer and chemist.
 Baldwin, Wm. A., 169, West 97th Street, New York, U.S.A., metallurgist.
 Bloede, Victor G., Patuxent and Dillon Streets, Baltimore, Md., U.S.A., manufacturing chemist.
 Bollough, Thos. A., Helsby View, Ditton, Widnes, engineer.
 Campbell, Jno. D., Crosby House, Thurlow Park Road, West Dulwich, S.E., technical chemist.
 Cliff, Cromwell, 30, Trentham Street, Runcorn, firebrick merchant.
 Coleman, Gurney F., University of Pennsylvania, Philadelphia, Pa., U.S.A., chemical student.
 Cunliffe, Jos., Rook Wood, Chorley, Lancashire, calico printer.
 Cunningham, A. Auchie, 13, Rutland Square, Edinburgh, analytical chemist.
 Curtis, Harry E., 1, Croft Villas, The Croft, Hastings, chemist and druggist.
 Duncan, Arthur W., 69, Market Street, Manchester, analytical chemist.
 Francis, Wm., jun., Chemical Laboratory, The University, Glasgow, chemist.
 Gunter, Evan, Nobel's Explosives Co., Ltd., Stevenston, Ayrshire, chemical engineer.
 Hall, Emile T., 1623, Spruce Street, Philadelphia, Pa., U.S.A., chemical student.
 Hecht, Jos., University of Pennsylvania, Philadelphia, Pa., U.S.A., chemical student.
 Heckmann, C., 9, Gortitzerufer, Berlin, S.O., Prussia, apparatus maker.
 Hooper, H. A., High Laboratory, Newcastle Chemical Co., Gateshead, analytical chemist.
 Horn, Wm., 156, Bath Street, Glasgow, analytical chemist.
 Hough, Oliver, 325, South 16th Street, Philadelphia, Pa., U.S.A., chemical student.
 Howorth, Franklin W., Lyme Grove, Church Road, Urnston, near Manchester, chemist.
 Jenkins, Thos., jun., Laboratory, Rio Tinto Works, Cwmavon, Port Talbot, Wales, chemist.
 Jones, John Arthur, Gijon, Spain, mining engineer and metallurgist.
 Kates, Clarence S., 1937, Spring Garden Street, Philadelphia, Pa., U.S.A., chemical student.
 Kent, Wm. H., Chaumont, Wokingham Road, Reading, Berks, head master.
 Leech, Fred. S., c/o B. G. Lemmon & Co., Cape Town, South Africa, chemist and druggist.
 Leese, Jos., Fylde Road Mill, Preston; and Palace Hotel, Birkdale, Southport.
 McArthur, Jno., 3, Nicosis Road, Wandsworth Common, S.W., chemist.
 McEwen, Jas., 11, Rushion Street, Hulme, Manchester, aerated water engineer.
 Master, Ardesheer B., 679, Tardeo, Bombay, India, manufacturer.
 Miller, Geo., 22, Trentham Street, Runcorn, Cheshire, chemist.
 Miller, Jno., Poynter, Sandilands Chemical Works, Aberdeen, chemist.
 Minatti, Theodore, Kenwood, Broom Lane, Higher Broughton, Manchester, chemist.
 Neilson, Thos., Distington Hematite Iron Co., Ltd., near Whitehaven, analytical chemist.
 Newbury, Spencer B., Cornell University, Ithaca, N.Y., U.S.A., professor of applied chemistry.
 Paterson, Alex., c/o B. G. Lemmon & Co., Cape Town, South Africa, chemist and druggist.
 Pattison, P. J., 11, Park Road, West Ham, E., chemist, colour.
 Peniston, A. H., 31, Disraeli Road, Upton, E., manager (Boor & Co.).
 Plumb, Ben M., Cowles Electric and Aluminium Co., 36, Lombard Street, E.C., managing director.
 Powell, Alf. E., 6, Dryden Street, Lonsight, Manchester, oil merchant.
 Reynolds, H. C., 8, The Avenue, Clifton, Bristol, retired army officer.
 Speckman, Jas., 7, Ward Road, Dundee, jute and oil merchant.
 Spoor, J. L., 30, Hotspur Street, Tynemouth, cement maker.
 Stroud, Walter R., 2035, Mount Vernon Street, Philadelphia, Pa., U.S.A., chemical student.
 Thomson, Dr. Andrew, 1, Blackness Crescent, Dundee, lecturer on chemistry.
 Walker, Jas. S. H., 304, Morningside Road, Edinburgh, chemical student.
 Wilson, Jos. A., Cross-fields, Tottington, near Bury, analyst.

CHANGES OF ADDRESS.

- Abraham, A. C., 10, Oxton; Stanley Rock, St. George's Mount, New Brighton (Journals); and 87, Bold Street, Liverpool.
 Beadle, Clayton, 10, Belvedere; c/o W. Joynson & Sons, St. Mary Cray, Kent.
 Bevan, Jno. W., 10, South View House; Avonmere, Shirehampton, near Bristol.
 Blackwell, G. G., 10, Chapel Street; 26-27, Irwell Chambers West, Fazerley Street, Liverpool.
 Budden, E. Russell; Camelot, Netherhall Gardens (not Terrace), South Hampstead, N.W.

- Byard, A. G.; Journal to Barriere des Minimes, Toulouse, France.
 Crane, Wm.; Journals to c/o Guillermo C. Tripler, Coquimbo, Chili.
 Crow, J. K., 10, West Drayton; Yiewsley, near Uxbridge.
 Divers, Dr. E., 10, College of Engineering; Hongo, Tokyo, Japan.
 Dixon, M. T.; Journals to P.O. Box, Johannesburg, South African Republic.
 Donald, W. J. A., 10, Belgrave Terrace; 27, St. Vincent Place, Glasgow.
 Dunn, Wm. Walton; Journals to 5, Cheapside, Tudhoe Grange, Spennymoor, co. Durham.
 Faulkner, F.; Journals to "The Laboratory," Langley, Oldbury, near Birmingham.
 Frankland, Dr. Percy, 10, London; University College, Dundee.
 Fulton, H. B., 10, Kirkintilloch; 33, St. Dunstan's Road, West Kensington, S.W.
 Grandage, H., 10, Bradford; Calder Dyeworks, Brighouse, near Leeds.
 Green, A. G.; Journals to 54, Thistlewaite Road, Lower Clapton, E.
 Greville, H. Leicester; Journals to 11, Lambton Road, Hornsey Rise, N.
 Hamilton, D.; Journals to 224, Ingram Street, Glasgow.
 Holland, Philip, 10, Albert Road; 3, Leicester Street, Southport.
 Hunter, F. W., 10, Newcastle; Newbottle, Fence Houses, co. Durham.
 Hutchinson, A. H.; Journals to 5, Derwent Grove, East Dulwich, S.E.
 Jenner, E., 10, Arthur Villa; Florence Villa, Murchison Road, Leyton, E.
 Lagerwall, Dr. Ivar, 10, St. Petersburg; 56, Rue de Joncker, Brussels.
 Langbeck, H. W., 10, Bromley by Bow; The Park, Loughton, Essex.
 Laurie, A. P., 10, Bayswater; Chemical Laboratory, People's Palace, Mile End Road, E.
 Leigh, C., 10, Sheffield; Seaham Chemical Works, Seaham Harbour, co. Durham.
 Lucas, Rich., 10, Middleton; 11, Dyne Road, Kilburn, N.W.
 Lunn, Collingwood, 10, Woodsome Lees; Penny Bridge, near Huddersfield.
 McKean, W.; Journals to Incandescent Gas Light Co., Ltd., 3, Victoria Mansions, Westminster, S.W.
 McKechnie, D. M., 10, Olive Mount; Roche Lea, St. Ann's, St. Helens.
 Mander, S. T.; Journals to Varnish Works, Wolverhampton.
 Marriott, Wm., 10, Belgrave Terrace; 88, Halifax Old Road, Huddersfield.
 Marsh, Walter, 10; 4; 83, York Terrace, Northam, Southampton.
 Mitchell, J. W., 10, Burnley Road; Holme Mill, Rawtenstall.
 Newton, A. H., jun., 10, Hampstead; 4, Croftdown Road, Highgate Road, N.W.
 Nishigawa, T., Journals to Go Bancho 14, Kojinachi, Tokyo, Japan.
 Norton, Prof. S. A.; Journals to 363, East Town Street, Columbus, Ohio, U.S.A.
 Palmer, T. C., 10, Haverstock Hill; 98, Commercial Road East, London, E.
 Pearson, Wm., 10, Mellor's Buildings; African Chambers, Old Hall Street, Liverpool.
 Pettigrew, Jno., 10, Stratford; 18, St. Helen's Place, Bishopgate Street, E.C.
 Saint, W. J., 10, Munich; Spitalstrasse 1, II., Erlangen, Bavaria.
 Saito, K., 10, Tokyo; Yosei Shikenjo, Osaka, Japan.
 Scott, G. H., 10, New Mills; 3, Alton Terrace, Fairfield, Manchester.
 Scrutton, W., 10, London; Aurora, Esmeralda Co., Nevada, U.S.A.
 Shapleigh, Waldron, 10, New York; Welsbach Incandescent Gas Light Co., Gloucester, N.J., U.S.A.
 Smith, Fred., 10, Sutton-on-Hull; Laboratory, 106, Queen Victoria Street, London, E.C.
 Smith, J. W., 10, Huddersfield; Massachusetts Institute of Technology, Boston, Mass., U.S.A.
 Stantial, F. G., 10, East Cambridge; c/o Cochrane Chemical Co., Everett, Mass., U.S.A.
 Thomas, Jos. W.; Journals to c/o D. R. Roberts, 10, Park Grove, Cardiff.
 Thomas, S. Percy, 10, Stratford; Chemical Laboratory, Royal Veterinary College, Edinburgh.
 Underwood, G. R., 10, Boston; Box 660, Peabody, Mass., U.S.A.

CHANGE OF ADDRESS REQUIRED.

- James, J. H., 10, 33, Old Broad Street, E.C.

Deaths.

- Bush, W. J., 20, Artillery Lane, London, E.C. January 10th.
 Young, Robt., 3, Radstock Road, Liverpool. September 3rd.

London Section.

CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: David Howard.

Committee:

Sir F. A. Abel.	R. Messel.
H. E. Armstrong.	B. E. R. Newlands.
W. Lant Carpenter.	B. Redwood.
W. Crowder.	T. Royle.
W. J. Dibdin.	John Spiller.
C. Graham.	Wm. Thorp.
S. Hall.	C. R. Alder Wright.
C. C. Hutchinson.	

Hon. Local Sec. and Treasurer:

Thos. Tyrer, Garden Wharf, Battersea, S.W.

SESSION 1888-89.

The Fourth Meeting of the Section will take place on Monday, February 4th, 1889.

Papers to be read by—

Dr. T. L. Thorne. "On some Industrial Applications of Oxygen."

Dr. J. Walter Leather. "Notes on Laboratory Apparatus."

Monday, March 4th, 1889.

DISCUSSION.—"In what direction is State Aid needed to assist Technical Education in Chemistry?"

Messrs. Higgins and Heron's paper on "Cider" is postponed.

Meeting held Monday, January 7th, 1889.

MR. DAVID HOWARD IN THE CHAIR.

ON A MODIFIED "ORSAT" APPARATUS.

BY JOHN RUFFLE.

On pages 47 and 84 of "Winkler and Lunge's Technical Gas Analysis," 1885, are cuts showing Orsat's apparatus for rapid estimation of oxygen, &c. in gases. On page 47 the parts marked *c*, *c'*, *c''*, and on page 84 the parts marked *h*, *d*, *e*, *b*, are bulbs of the shape as in the below Figure No. 1 (side view):—

Fig. 1.

The part A is filled with short lengths of very narrow glass tubing, which, when wetted by the reagent used in the analysis—caustic potash, pyrogallate of potash, &c.—provide a large absorbing surface; B is a reservoir for the solution when it is driven out of A. The gas to be examined enters and is withdrawn through a capillary tube at C. The weight of the glass tubing in A presses on the joints at D and E, whilst the weight of the solution when in B presses on the joints at the bend F and G. These parts are therefore weak, and are, in practice, found to break easily and frequently, especially if the apparatus has to be carried about. Even when used in one place the filling and emptying, cleaning, &c. too frequently results in a breakage; also in manufacturing, the final fixing of the capillary tube C is found extremely difficult, and many bulbs are spoiled through the bulk of the tubing in interior of A prematurely cooling the glass and causing fracture, adding materially to the expense of the apparatus.

To avoid these numerous breakages, and make the whole easier and simpler to manufacture and work, I have adopted the form of bulb in Figure No. 2.

A is an upright cylinder closed at bottom, B is a cylinder-shaped bulb with open mouth at bottom and is at C suspended to D by india-rubber tubing, so that its open mouth is kept about a quarter of an inch from the bottom of A. B is nearly filled with a number of short pieces of narrow glass tubing, C is a capillary tube, and, by it, the gas to be tested is passed in and out.

This form of bulb allows the whole weight of the

Fig. 2.

solution and of the glass tubing to rest on the flat bottom of A, and, this standing on a piece of board, gives the whole a firm support. It is not easy to break, can be carried about without anxiety, and is easily and readily cleaned. The manufacture of such shaped apparatus is easy, so tending to cheapen it.

F and G are duplicates of A and B.

H is the usual 100 cc. pipette to measure off the 100 cc. of gas to be analysed. A, B, F, and G, are in due proportion to allow the 100 cc. to be manipulated.

This form of bulb answers very well; the 100 cc. of gas when passed out of H goes through D and C into B, causing the solution of caustic potash, &c. (with which B has been previously filled) to fall in B and rise on the outside in A around B. The gas passing back into H allows the solution to flow back from A into B, which is then ready for the next trial.

However simple an apparatus may be, it often happens that it is broken, and much inconvenience arises through sending to the makers for repairs. In view of this, Mr. James MacLachlan has proposed an arrangement which, as long as its joints are kept tight, is thoroughly efficient and has the great advantage of being easy to find and to replace in any factory. Figure No. 3 is a side view:—

Fig. 3.

It consists of two 4 oz. bottles, A and B, with pieces of glass tubing in A. In the mouth of B is a two-holed cork with an air tube C in one hole, and in the other a syphon tube, the limbs of which are of about equal length; one reaches nearly to bottom of B, the other passes through a hole in the two-holed cork in neck of A, and goes nearly to the bottom of A. The other hole in the cork of A is filled by a piece of capillary tube and attached by a piece of india-rubber tubing to the supply capillary tube D, as in preceding figures. The gas to be examined is forced from the 100 cc. measuring tube into A, forcing out the solution of potash, &c. previously filled in) through the syphon tube into B, and, after due exposure, the gas, on withdrawal, draws back the solution from B into A. These 4 oz. bottles are cheap, easy to obtain, and stand firmly.

It would be to the advantage of sulphuric acid makers if they were to use an "Orsat" or some similar apparatus for examination of their kiln and chamber gases, &c. instead of working by rule of thumb as so many do. Frequently they say "we use as little nitre and are doing as well as so and so," not thinking that by due examination of their gases and use of a little common sense a higher efficiency and economy could be obtained.

Mr. A. E. FLETCHER said he could testify to the utility of the Orsat apparatus. The convenience found in its use made it very suited to the needs of large coal consumers, many of whom were now finding the advantage of making frequent examination of their gases of combustion. Professor Lunge had added to the apparatus originally devised by Orsat, a tube containing palladium-asbestos. The gas remaining after the absorption of the CO_2 , CO , and O , originally contained in it, was mixed with air and passed through this tube, previously heated by means of a spirit lamp. The hydrogen was thus burnt and its volume estimated.

It could hardly be said that the form of the absorbing glasses now shown was new, as the diving-bell arrangement had been in use many years. In the apparatus used by himself the cylinders were kept from the air by means of a rubber cover connected with a small bladder. In some forms of the apparatus the stop-cocks were dispensed with, small beads of glass inside the connecting rubber tubing

taking their place, as in the case of the Mohr's burette. A slight pressure of the fingers outside the tube made a passage for the gas by the side of the glass bead. Thus, all chance of a leaky stop-cock was avoided. Since water and not mercury was used in the measuring vessel, objection might be taken to the possibility of error arising from the absorption of carbon dioxide.

ON THE ESTIMATION OF GLYCERIN IN SOAP LYES AND CRUDE GLYCERIN.

BY OTTO HEHNER.

GLYCERIN in its various stages of purification, as soap lyes, crude, dynamite, and pure glycerin, has of late years become an article of commerce of very considerable importance. There are now, happily, but very few, if any, manufacturers of soap who do not utilise their liquors for the preparation of glycerin in some form or other. Some may prefer to sell their concentrated liquors, others to refine them, but all endeavour to obtain the utmost value for the substance which, until quite lately, was ignorantly thrown away.

With this progress accurate direct processes for the determination of the percentage of the glycerin itself were naturally felt to be required, and the indirect methods of valuing the articles in which glycerin is the essential constituent, became insufficient. The specific gravity, together with the boiling point, or boiling point and ash, sufficient as guides to the manufacturer, gave indications too crude and indefinite to serve as means to arrive at exact commercial values, the specific gravity and boiling point being largely influenced by the quantity of valueless impurities present, such as fatty acids and resinous substances, and by the quality and composition of the saline constituents which are contained in every soap lye to a very large amount.

A number of methods of glycerin estimation have in consequence been more or less worked out, but their agreement among themselves, or in different laboratories, is frequently so unsatisfactory, that disputes between manufacturers and buyers continually arise, occasioning pecuniary loss to the merchants and discrediting the analysts with both parties concerned. It is therefore extremely desirable that some kind of an agreement be arrived at with a view to eliminate processes which do not answer the present requirements. In this hope I venture to bring forward some of my experiences in this matter, without pretence of having exhaustively investigated so difficult a subject.

The chief methods to be considered are the following:—

- (1.) The extraction of glycerin from the concentrated liquors by means of alcohol and ether, and its direct determination by evaporation.
- (2.) The conversion of glycerin into mono-phalbic glycerin by lead oxide.
- (3.) Oxidation by bichromate.
- (4.) Conversion into triacetin by acetic anhydride.

1. Direct Extraction.

The specific gravity of the sample is taken, from 20 to 25 cc. are pipetted into an evaporating basin, then neutralised with dilute sulphuric acid should the liquor be alkaline (which is usually the case), and evaporated on a water-bath to a syrupy consistence. After cooling, a mixture of one part of ether and two of alcohol is added, and the saline precipitate is well broken up by means of a small pestil. Filter into a

weighed beaker, and well wash the precipitate with ether-alcohol. The solvent is then evaporated on the water-bath, and the residue is heated to 110° C. until the weight is as constant as possible. In this residue the ash must then be determined, and subtracted from the total weight, the remainder being taken as pure glycerin.

The defects of the method are twofold:—Ether-alcohol extracts not only the glycerin, but a considerable portion of the organic impurities of the crude sample, and these are counted as glycerin. The fatty and resinous matters, as far as they are soluble in the neutralised glycerin, are so counted. On the other hand, loss by volatilisation cannot be avoided, counterbalancing the former error to a more or less extent, and generally exceeding it, so that the results are, as a rule, too low, as indeed are those of all direct extractions.

On the subject of volatility of glycerin I may here refer to some results of mine which I have previously published in the "Analyst" (Vol. xii., p. 65).

There cannot be a doubt that glycerin is volatile, for on heating concentrated glycerin solutions on a water-bath thick white fumes of glycerin can be seen to be given off, and the weight of the glycerin diminishes considerably and constantly. But it is generally believed that even dilute aqueous solutions of glycerin lose considerably by boiling; that, in fact, glycerin is volatile with aqueous vapour. This belief rests upon no solid foundation. From solutions containing as much as 50 per cent. of glycerin, no glycerin is expelled by two hours' boiling if care is taken that the escaping water is continually replaced. Even a 74 per cent. solution suffers under these circumstances but a most trifling loss, amounting to from 1 to 2 per cent. only. The volatility commences when solutions have obtained a higher concentration than this, and at temperatures beyond 100°, say at 110°, as prescribed and practised in large continental dynamite works, the loss is anything the operator may like to make it.

Unless the final evaporation of the ether-alcohol and water be performed in vacuo, the direct extraction method is therefore quite useless, but against this refinement of the process the length of time requisite for the analysis materially militates.

2. The Lead Oxide Method.

Two grms. of the sample are mixed with about 40 grms. of pure litharge, and heated in an air-bath to 130° C. until the weight becomes constant, care being taken that the litharge is free from such lead compounds and other substances as might injuriously affect the results, and that the heating of the mixture takes place in an air-bath free from carbonic acid. The increase in weight of the litharge minus the weight of substance not volatilisable from 2 grms. of the glycerin at 160° C., multiplied by the factor 1.243 is taken as the weight of glycerin in the 2 grms. of the sample.

In very many cases this method gives very good results, well agreeing with those obtained by the other methods to be considered. In other cases the agreement is not so satisfactory.

In glycerins of fair purity, containing almost exclusively sodium chloride and glycerin, and but little other organic matter, the method operates well. But in samples containing notable quantities of free alkali, of sulphates, or of resinous matters, the results are, in my opinion, faulty. From such samples it is wellnigh impossible to volatilise the whole of the glycerin at 160°, even by very long continued heating. Consequently there is a tendency to obtain results which are too low. On the other

hand, it being all but impossible to construct an air-bath in which there is no carbonic acid, which is absorbed by the free caustic alkali either naturally contained in the article or formed by the action of the lead oxide upon the sulphates, there is a counterbalancing influence.

The method enjoys extensive use, but it is so slow, and open to so many objections, that I cannot consider the results obtained by means of it as absolutely trustworthy.

3. The Bichromate Method.

Pure glycerin, heated with bichromate and sulphuric acid, is quantitatively oxidised to carbonic acid, as I have shown by numerous experiments previously published (Analyst, XII., p. 44). In the case of very strong and pure glycerins the carbonic acid evolved may be measured or weighed, as proposed by Cross and Bevan, and Legler, but in impure and crude glycerins previous preparation of the sample and removal of impurities is necessary, causing such dilution of the sample that the carbonic acid evolved cannot be conveniently estimated. I prefer to operate as follows:—

Solutions required:—

1. Bichromate, containing in each litre about 74.86 grms. of bichromate and 150 cc. of strong sulphuric acid. The exact oxidising value of the solution must be ascertained by titration with solutions of known quantities of iron wire, or pure ferrous ammonium sulphate.
2. Ferrous and ammonium sulphate solution containing about 240 grms. per litre.
3. Bichromate solution ten times more dilute than the above. The ferrous solution is exactly standardised upon the chromate solution, and the glycerin value of the chromate (contents of bichromate divided by 7.486) is calculated.

With pure glycerins the oxidation is absolutely quantitative.

Crude glycerins must be treated as follows:—For the removal of chlorine and of aldehydic compounds some oxide of silver is added to a weighed quantity of the sample (about 1.5 grms.), which is placed into a 100 cc. flask. After slight dilution the sample is allowed to stand with the silver oxide for about ten minutes. Basic lead acetate is then added in slight excess, the bulk of the fluid made up to 100 cc., and a portion is filtered through a dry filter. 25 cc. of the filtrate are placed into a beaker, previously well cleaned with sulphuric acid and bichromate to remove all traces of fat, from 40 to 50 cc. of the standard bichromate solution are added, accurately measured, then about 15 cc. of strong sulphuric acid, and the beaker, covered with a watch glass, is heated for two hours in boiling water. After that time the excess of bichromate is titrated back with ferrous ammonium sulphate solution.

As the bichromate solution is necessarily a somewhat strong one, the measuring must be done with the greatest care; some attention must be paid to the temperature at the time of measuring. I find that a bichromate solution of the strength indicated expands for each degree C. .05 per cent.

The results upon repetition agree well. Instead of basic lead acetate, copper sulphate and potassium hydrate may be used for precipitation of organic impurities, but I prefer, and always use, the former.

Practically the method is rapid and presents no difficulty whatever. It is open to the objection that by precipitation by lead the impurities may not be perfectly removed, anything left being oxidised and counted as glycerin. All higher fatty acids and all resinous acids, as well as albuminoids, sulphides,

sulphocyanates, and aldehydes, are, however, completely removed, and the lower fatty acids, such as acetic and butyric, are not attacked by bichromate. The filtrates after precipitation are perfectly colourless.

In the earlier stages of my experience with this method no special precaution was taken to guard against the evolution of chlorine during the oxidating. Indeed, experiments made to test the influence of free hydrochloric acid, although giving results slightly too high, seemed to show that free hydrochloric acid was without influence on the result.

Later experiences caused me to modify my opinion, as in the case of crude glycerins containing much sodium chloride an odour of chlorine could sometimes be observed. This loss of chlorine is slight when the liquor is heated, as described, in boiling water, but becomes notable when it is boiled over the naked flame. Thus two oxidations of the same sample, without silver oxide, furnished 82.69 per cent. of glycerin on the water-bath, and 83.83 per cent. over the naked flame. The addition of oxide of silver removed this possible source of error.

Nevertheless, the force of the theoretical objection that the precipitation of impurities, which might increase the result, is incomplete, must be allowed. I will, however, show subsequently that the objection is a merely theoretical one.

4. The Acetin Method.

This method, quite lately published by Benedikt and Cantor, depends upon the conversion of glycerin into triacetin and the saponification of the latter, and reduces the estimation of glycerin to an acidimetric operation.

About 1.5 grms. of the crude glycerin are heated to boiling with 7 grms. of acetic anhydride, and 3 to 4 grms. of anhydrous sodium acetate under an upright condenser for 1½ hours. After cooling, 50 cc. of water are added, and the mixture heated until all triacetin has dissolved. I prefer not to boil, as described by the authors, because triacetin rapidly hydrolyses.

The liquid is then filtered into a large flask, the residue on the filter is well washed with water, the filtrate quite cooled, phenolphthalein is added, and the fluid exactly neutralised with a dilute (2—3 per cent.) alkali solution, the strength of which need not be exactly known. 25 cc. of a 10 per cent. caustic soda solution, which must be accurately standardised upon normal acid, are then pipetted into the liquor, which is heated to boiling for 10 minutes to saponify the triacetin, and the excess of alkali is then titrated back with normal acid. 1 cc. of normal acid corresponds to .03067 gm. of glycerin.

The method is rapid and extremely simple. With certain precautions the results are quite concordant.

These precautions are:—

The heating at the various stages of the operation must be done under the reflux condenser, the triacetin being somewhat volatile.

The sodium acetate used must be quite anhydrous. The salt purchased as anhydrous has never by me been found to be so. It must therefore be freshly and cautiously heated before use. If this be not done the conversion of the glycerin into the triacetyl compound is imperfect. Thus a sample of pure glycerin, containing 98.5 per cent. of real glycerin, yielded the following results:—65.9, 72.2, 74.4, and 66.0 per cent. of glycerin; another sample, of crude glycerin, with 79.2 per cent. of real glycerin, gave 67.6 per cent., imperfectly dehydrated acetate being used before my attention had thus been drawn to the importance of the precaution.

Triacetin in contact with water gradually decomposes. Hence, after acetylation is complete, the operations must be conducted as rapidly as possible. This necessity is illustrated by the following figures. A crude glycerin by the acetin method, properly carried out, was found to contain 80.9 per cent. of glycerin. When 15 minutes were allowed to elapse, after addition of water to the mass containing acetic anhydride, only 78.3 per cent. were found; after one hour only 76.9. In the case of another sample, with 79.7 per cent. of real glycerin, 77.7 per cent. were found after one hour's standing. And, lastly, in a sample with 84.0 per cent., only 79.6 were found after one hour.

More marked still is the action of alkali upon the triacetin, and it is necessary therefore to neutralise the free acetic acid after acetylation as cautiously as possible, and with rapid agitation of the diluted liquor, so that the alkali may not be locally in excess more than is unavoidable. The determination becomes quite inaccurate if the fluid is over-neutralised, even if the excess be titrated back as rapidly as possible. A sample of concentrated soap lyes, which, when properly analysed, gave 50.9 per cent. of glycerin, showed but 40.9 in an experiment where over-neutralisation was allowed to take place for a very short time.

It is seen that however perfect the method may be theoretically, practically it has a tendency to yield results somewhat below the truth.

I need not in detail refer to the permanganate method, originally proposed by Fox and Wanklyn, and afterwards modified by Benedict and Zsigmondy, which depends upon the oxidation of glycerin into oxalic acid by means of alkaline permanganate. The method has been abandoned by Benedict himself in favour of the acetin method, and has never, in my hands, given anything like accurate results.

I have compared the bichromate method, as used by myself, and the triacetin method in a large number of cases, and give, in the following table, some of the results:—

	Bichromate Method.	Acetin Method.
Pure glycerin.....	98.48	98.5
" "	98.58	
" "	98.53	
Crude glycerin, without use of Ag_2O	80.25	97.9
" "	80.39	
" "	80.39	
Same, with Ag_2O	79.19	79.25

The general agreement between these results is very marked, the differences in most cases being evidently within the range of experimental errors. This agreement between the results of two methods so widely different in principle shows that both methods measure, as nearly as possible, the real glycerin present. To ensure the greatest amount of accuracy, I advise always to use *both* methods upon any sample to be analysed, and to take the mean of the two results.

In the case of very dilute liquors, such as the unconcentrated soap lyes, previous concentration of the sample to about 50 per cent. of glycerin is necessary with the acetin method, which fails when the proportion of glycerin falls as low as 30 per cent. In such cases I prefer to use the bichromate oxidation only.

The estimation of glycerin in fats and soaps is carried out as follows:—Saponify about 3 grms. of the fat with alcoholic potash solution; do not drive off the alcohol, but dilute the soap solution to about 200 cc.; decompose with dilute sulphuric acid, filter off insoluble acids, which may be estimated as usual. Then vigorously boil the filtrate and washings, amounting altogether to about 500 cc., in a covered beaker down to one-half, then add sulphuric acid and standard bichromate as described. A few results thus obtained are as follow:—

	Glycerin.
Olive oil.....	10.26
Cod liver oil.....	9.87
Linseed oil.....	10.24
Margarine.....	10.01
Butter.....	12.4
"	11.96

It may be worth while to refer to two other points on which manufacturers of crude glycerin generally desire information, namely, the percentage of salts and the specific gravity.

Both determinations should and do not present any difficulty, yet wide discrepancies not unfrequently occur when the same sample is placed into the hands of different chemists. This is a matter of some importance, because the sale contracts generally contain some clause limiting the admissible percentage of salts.

A sample, drawn from bulk, yielded me 11.26 per cent. of salts, to a well-known firm of chemists, Messrs. Teschemacher and Smith, only 9.00 per cent. Another sample, from the same manufacturers, to myself, 10.75, to Messrs. Teschemacher, 10.05 per cent. Duplicate samples were then placed into the hands of Mr. Norman Tate and Mr. Bernard Dyer, who found 10.78 and 10.85 per cent. respectively.

The obvious precaution in estimating percentage of salts is never to allow the platinum dish in which the sample is burnt to become red hot, but to burn over an Argand burner at the lowest possible temperature. 1 to 2 grms. of crude glycerin generally burn white in from one to two hours, if the dish

be covered with a platinum lid: frequently much more quickly.

Mr. H. D. Richmond estimates the ash more expeditiously and hardly less accurately, by carbonisation of the sample, and the addition of a little strong sulphuric acid, the residue being burnt white over a good Bunsen flame. The sulphated ash, multiplied by .8, closely agrees with the ash found without sulphating, although in the products of different manufacturers slight variations in this respect may be observed, as is seen from the following table of results:—

CRUDE GLYCERINS.

Sample.	Ash.	Sulphated.	Multiplied by .8.	Difference.
1	12.29	15.40	12.32	+ .03

29	10.68	12.90	10.32	— .36
30	10.76	12.98	10.38	— .38

The theoretical factor, assuming that the whole of the ash consisted of sodium chloride, would be .824.

The factor for glycerins made by one and the same manufacturer is fairly constant, most of the above samples which furnished low figures by the sulphuric acid method coming from one works.

The specific gravity is generally taken in glycerin works by means of the specific gravity balance. An excellent form of instrument is made by Sartorius, of Göttingen. In consequence of the great viscosity of glycerin the balance works, however, very slowly, and variations in the reading, amounting up to .002,

are observed. For these reasons I prefer the use of a Sprengel tube, which is filled by means of an air pump with the glycerin previously heated, to reduce viscosity, in a closed flask, on the water-bath. The tube is then immersed in water of 15.5°. Should the temperature be not exactly 15.5°, a correction in the gravity may be made of .00058 for each degree C.

The specific gravity of pure glycerin, of course, is a measure of the glycerin itself. A number of very contradictory tables have been published; the one which, according to my experience, is of satisfactory accuracy being that of Lenz (Zeits. Anal. Chem. XIX., page 302). Lenz, however, took his specific gravities at temperatures varying from 12°—14° C. By means of the above factor Mr. H. D. Richmond has recalculated Lenz's table to 15.5° C.

Percentage.	Sp. Gr. at 15.5°.	Percentage.	Sp. Gr. at 15.5°.
100	1.2674	87	1.2327
99	1.2647	86	1.2301

88	1.2353	75	1.2011

I will illustrate the discrepancies, by no means uncommon in the analysis of glycerin, by a recent case, which may be taken as a typical one.

A consignment of crude glycerin sent from England to Hamburg was analysed by five different chemists, all operating upon identical samples.

	Glycerin.
	Per Cent.
1. The purchaser's chemist found.....	71.9
2. Dr. Fresenius.....	73.74
3. Schalkwyk and Pennink, Rotterdam.	76.63
4. N. Tate.....	77.24
5. Hehner	(a) 80.32
	(b) 79.35
	(c) 79.29

Chemist No 1 uses the direct alcohol-ether extraction; Professor Fresenius the permanganate process; Schalkwyk and Tate the lead oxide method. My own figures, higher than any of the other chemists, were obtained (a) by oxidation by bichromate without the use of silver oxide; (b) by bichromate with silver oxide; (c) by the acetic process. No agreement, except of the two latter estimations, is observable in the above series of analyses.

I hope that my observations will lead to something like agreement between different analysts as to the mode of procedure to be adopted. My own recommendations are—

The use of both bichromate and acetic anhydride methods, taking the average of the results.

The sulphatising of the ash, as this excludes almost all possibility of difference between two observers.

I gladly express my thanks to my assistant, Mr. H. D. Richmond, who has carried out most of the analyses, the results of which are given in this paper, and who has aided me throughout my investigations on the subject.

DISCUSSION.

The CHAIRMAN said it was most useful and interesting to have such papers as that presented by Mr. Hehner, throwing light upon rare methods of analysis. It was a striking evidence of the advance of industrial chemistry that such analyses as Mr. Hehner had described should be called for; not many years ago they would have been quite needless, for the industrial use of glycerin had begun well within his memory. As out of the way products, such as glycerin once was, were introduced into industrial work and grew in importance, it of course became necessary that really accurate methods of analysing them should be discovered. The two methods described by Mr. Hehner had this great advantage, that while producing thoroughly concordant results, they were of a totally different nature. By merely varying the same method, one might without much difficulty get results according with each other, but in such cases there was always ground for suspecting that there might be the same source of error in each analysis and therefore remaining undiscovered. But when the two methods employed were so essentially different, the probability of the common result being correct was enormously increased. He thought, therefore, that Mr. Hehner had demonstrated the superiority of the two methods which he proposed.

Mr. W. F. REID, having had considerable experience of the practical tests used by the largest consumers of glycerin, the dynamite manufacturers, thought it might interest the meeting to hear some account of those processes. In the first place, all scientific analytical tests such as Mr. Hehner had described were regarded as almost useless in the dynamite factory. They used such methods as far as possible, but they mainly depended on a series of practical tests. The first step was to ascertain the amount of chlorine in the glycerin. If a sample showed much chlorine, it was at once rejected, chlorine being one of the greatest sources of danger in a dynamite works. The next test was to gently warm the glycerin with sulphuric acid. If it discoloured the acid much, the glycerin was rejected as being likely to cause heating in the nitrating vessel. For the detection of the fixed substances they heated the glycerin in a platinum capsule. They did not take the great precautions indicated by Mr. Hehner during this evaporation, and no doubt small portions of the mixed substances passed off with the glycerin. But they did not trouble about that. If they found an appreciable residue they rejected the glycerin, not on account of the danger, but as containing impurities in themselves useless. Of course crude glycerin was not used for nitrating purposes, as it would be dangerous. They tested that body practically by distilling it in superheated steam. That was the best test of its suitability for manufacturing purposes. There might be a certain percentage of pure glycerin in a crude glycerin; but there were also complex organic bodies present which destroyed a proportion of the glycerin on distillation, and thus prevented the manufacturer from getting the yield of pure glycerin which analysis indicated as being obtainable. The final test of the pure glycerin was nitration. Nitration was done in the ordinary way and with the usual acids used in the factory. He

had tested a number of the analytical methods mentioned by Mr. Hehner, and had found them all wanting. He hoped that Mr. Hehner's new methods would prove more successful: in the meantime, however, he should adhere to the old practical tests of the dynamite makers.

Dr. C. ALDER WRIGHT said that he could not claim much acquaintance with the most recent processes for the analysis of crude glycerins and distilled glycerins, his own experience having been chiefly confined to glycerin extracted from soap lye in the ordinary way, and examined by the older methods. In one respect, however, his own experience agreed with Mr. Hehner's, namely, that a dilute solution could be evaporated down without any appreciable loss of glycerin—though without doubt volatilisation did take place when glycerin was concentrated. He would like to ask the last speaker (Mr. W. F. Reid) what was the relation between the practical yield of nitroglycerin obtained by nitration after the purification of crude glycerin by distillation, and the values given by accurate analytical processes. To a manufacturer he supposed that, as a rule, it was a matter of less interest to know what was actually contained in his crude material than what could practically be got out of it; just as an alkali maker would not so much want to know for ordinary purposes the total sodium carbonate in his black ash as how much could in practical working be dissolved out by water; the proportion retained undissolved as double carbonate of sodium and calcium being of less moment to him. Similarly in the case of the preparation of quinine, he thought the Chairman would agree with him that usually it was the amount of quinine that could be extracted by practical working processes that was important rather than the determination of the absolute quantity of quinine in the bark by some method not available in actual manufacture. He was, therefore, desirous of learning what relation the results of these rough practical tests bore to those of the refined methods described by Mr. Hehner.

Mr. W. F. REID said that with the permission of the Chairman he would answer Dr. Wright's question at once. The practical yield was always lower, because of the solubility of the nitroglycerin in the acids which were used to nitrate it. They had tried to precipitate the nitroglycerin from the acids by dilution with water, but had found it to be also to some extent soluble in the acid water; so that only a small proportion of the dissolved nitroglycerin could be recovered in that way. The best method was to freeze the solution. He was quite aware that the tests he had described could not be considered accurate quantitative methods; but they were tests which enabled manufacturers to know what results to expect in actual working, those results being always considerably below the theoretical yield of pure glycerin,—roughly speaking, he would say at least 5 per cent. below it.

Mr. S. HALL (E. Rider Cook and Co.) said that he could confirm Dr. Wright's remark that there was very little loss of glycerin in evaporating dilute solutions—up to about 75 or 80 per cent. That was his experience of working on the large scale. He had tested large quantities of lyes, and determined the glycerin by the lead method, and had usually found the loss from an 80 per cent. solution to be under 1 per cent.

Mr. HEHNER, in reply, said that his paper was strictly confined to the estimation of glycerin in crude glycerides, whereas the remarks of Mr. Reid related almost entirely to the testing of dynamite

glycerins, which was quite a different matter. The fitness of a glycerin for dynamite manufacture depended upon its *purity*. Such glycerins should not contain more than mere traces of salts, whereas all the glycerins he had spoken of contained about 10 per cent. of salts. He might thus dispose of Mr. Reid's remarks as being founded on a misconception of the purpose of his paper. But apart from that, he felt bound to protest against the idea that the practical results of distillation should override the scientific methods of estimating the glycerin itself. If he, as an analyst, was required to state the amount of loss of glycerin which every manufacturer would incur in working, he would prefer to give up glycerin analysis altogether. The amount of loss must depend upon careful or careless working; in the one case it might be very low, in the other case very high; but that was the manufacturer's business and not the analyst's. It must be remembered that the glycerin industry was comparatively new. If they allowed the theory to take root that although there was a certain percentage of glycerin present, manufacturers could only expect to get out so much less, improvement would be stopped and the whole industry would go to sleep. Manufacturers ought to get *all* out if possible, and therefore he endeavoured to tell them exactly how much was present.

Mr. A. H. HUTCHINSON inquired whether Mr. Hehner's crude glycerins were alkaline, acid, or neutral. To which Mr. Hehner replied that they were generally alkaline; but that their condition in that respect depended on the stage at which they were received from the manufacturer.

The CHAIRMAN, in proposing a vote of thanks to the author, said that he sympathised with the views of both Mr. Hehner and Dr. Wright. It was desirable that the manufacturer should be informed on both points:—What the crude material he bought consisted of, and what he ought to get out of it; and the nearer he got his practical results to agree with what they ought to be the better for him. There were certain analytical processes which were not commendable theoretically, but which were useful because manufacturers knew what they meant; and in his opinion it was better to have even an imperfect analysis of *constant* inaccuracy than to have an uncertain analysis of theoretical accuracy.

Mr. CROWDER then opened the discussion of which he had given notice, and in doing so, said that he had introduced the subject in this way rather than by the usual method of reading a paper, he having noticed in the *Engineer* that such a course was being pursued by one of the American Societies, in which any member was at liberty to raise a question of general interest to the Society, and to have it discussed under certain regulations. It was for the members to say whether they thought it desirable that questions should be raised and discussed in a similar way in this Society. He had selected this particular subject, having experienced considerable irregularity in the working of sulphuric acid chambers in summer time. Some manufacturers had assured him that if the acid was cooled, say to 40° or 50° Fah., before going down the Gay-Lussac tower, a better absorption would be obtained than with an acid at 120° Fah. But on reflection the matter did not appear to be quite so certain. If hot

hydrochloric acid was run down a tower, and ammonia passed in, the acid and ammonia would combine, probably as well as if a cooler solution were used. On the other hand, if carbonic acid was passed into the tower with hot water, no absorption would result, whereas an absorption *could* be obtained by using cold water. He thought the difference arose from the fact that in the one case nothing but a weak solution occurred, whereas in the other a fixed substance (ammonium chloride) was formed. In passing nitrous acid through sulphuric acid one got a similar result, viz., a fixed and stable substance. That it was stable he thought there could be no doubt. Lunge so stated it, and he had himself made experiments confirming Lunge's statement. He had taken strong nitrous acid solution in SO_2 from the Gay-Lussac tower, and heated it to about 220° Fah. for nine hours. He had tested the acid before and after heating, and found no difference in the quantity of nitrous acid in it, thus showing that nitrous acid was held with great tenacity. If he had raised the temperature of a solution of carbonic acid to any extent the acid would have passed off at once. He therefore asked whether any members had experience as to the *maximum* temperature at which acid could be economically absorbed in the Gay-Lussac tower; and if a much better absorption could be got at a very low temperature, then what was the best way of producing that temperature. Under ordinary circumstances the cooling water was taken from the ground or from the water company's mains, and was at about the same temperature as the atmosphere at the time, so that under such conditions one could not get a temperature lower than that of the water—indeed, the difficulty was to get it even as low as that.

The CHAIRMAN hoped that any members who had practical experience on the subject would give the meeting the benefit of it. The question was one of considerable interest and importance. Of course, there was a distinction to be made between mere solution and combination, whether molecular or chemical. In fact, the whole question of successful condensation depended upon whether one was dealing with a mere solution or a combination of a closer and more permanent character.

Mr. B. E. R. NEWLANDS regretted that his friend, Mr. Crowder, had chosen this method of raising the question of acid absorption. It was, he thought, an undesirable course to take, because it placed members who had special knowledge of the subject in an awkward and false position. If Mr. Crowder had read a paper on the subject and had given the Society the benefit of a full description of his own work in connexion with it, there would probably have been a large meeting and an ample discussion, by which all parties interested would have profited. But he felt sure that those members who were best qualified to speak were adverse to imparting their knowledge in this way. With respect to Mr. Crowder's own remarks on the subject, he did not think that the experiment on hot nitrous vitriol had much bearing on the question at issue. The fact that vitriol could contain certain compounds of nitrogen in a combined state was admitted. It was not a case of mere solution, and it was well known that such compounds were not decomposed by moderate heating. But whether or not nitrous gases could be absorbed by vitriol at a high temperature was quite a different matter, which had not, he thought, been decided by Mr. Crowder's experiment. He had himself a strong belief, founded on experience, that the acid could not be got too cold. He also thought

that the method now generally used for cooling the acid, by circulating it through channels having partitions of lead dividing the acid from a current of cold water, was by no means a good one. The mere fact that lead possessed only about one-fifth the heat-conducting power of copper showed that it was a bad material for such a purpose. Although the water often entered the apparatus at the freezing point and was in contact with acid of about 290°, it seldom left it at a higher temperature than 150°. If the end of the apparatus were made of copper, and the acid at 140° or 150° were made to pass through it, the operation of cooling would be greatly facilitated and the acid would be reduced to a temperature approaching that of the water used for cooling it.

Mr. C. C. HUTCHINSON inquired how the nitrous acid would act on the copper tubing, to which Mr. Newlands replied that inasmuch as he was speaking of acid which had left the Glover tower, he assumed it to be sulphurous and not nitrous.

Mr. C. C. HUTCHINSON said that copper tubes were now obtainable up to 9 inches in diameter, and he hoped in a few years' time to see brazed copper tubes go out of existence altogether.

Mr. B. E. R. NEWLANDS further remarked that it was well known, too, that sulphuric acid could be, and was, at ordinary temperatures, safely carried in copper drums.

Mr. CROWDER, in replying, thanked Mr. Newlands for his valuable contribution to the discussion. He regretted that so few members had taken part in it, but supposed that was due to the feeling suggested by Mr. Newlands. With regard to what had been said about copper tubes, he must confess that he would be somewhat afraid to pass warm sulphuric through them. He knew that acid, after cooling, could be conveyed by railway in copper vessels, and had himself used large copper tanks on wheels for that purpose. But then the copper was from $\frac{1}{4}$ to $\frac{1}{2}$ inch thick.

Mr. NEWLANDS said that there was no action on such drums, and their thickness affected only their strength.

Mr. CROWDER, continuing, said the great difficulty was to continue the cooling of the acid below 100° or 120° Fah. The nearer the temperatures of the acid and the water approached, the more difficult it became to further reduce that of the acid.

DR. F. HURTER IN THE CHAIR.

THE PARNELL AND SIMPSON ALKALI AND SULPHUR PROCESS.

BY E. PARNELL, F.C.S.

THE subject of the paper I have the honour to read before this Section of our Society this evening is a process for the manufacture of alkali by means of carbonic acid gas from brine and ammonium sulphide, with the recovery of the sulphuretted hydrogen evolved in the reaction, the ammonium sulphide being produced by the distillation of the ammonium chloride produced in the process with Leblanc alkali waste. The first patents in connexion with this process were taken out early in 1885, since which time the practical development has suggested several important alternative methods and improvements, and the total number of patents now amounts to about 15.

The process closely corresponds to the well-known ammonia-alkali process, bicarbonate of soda being precipitated from the brine and ammonium sulphide by the action of the carbonic acid in the same way as it is from brine and ammonia in the ordinary process, while calcium sulphide or Leblanc alkali waste takes the place of lime in the distilling operation.

In order clearly to explain the working of our process, and also for purposes of comparison, it may be well to first briefly describe the most successful method of working the ordinary ammonia process, namely, the system introduced by M. Solvay, which is now so largely used in this country, on the Continent, and in America.

The ammonium chloride liquor is introduced in a continuous flow into the top of a vertical tower of wrought or cast-iron, about 8 feet diameter, and about 40 feet high; this tower is divided into compartments, communicating with each other by suitable openings. Milk of lime at the same time is continuously fed in such proportion as to decompose the whole of the ammonium chloride, and steam is admitted at the bottom. The ammonia liberated by the lime passes off in the form of gas from the upper part of the still, and is condensed in brine in a suitable cooling apparatus. By the time the liquor reaches the bottom of the still it is thoroughly freed from ammonia by the ascending steam, and is from time to time drawn off and allowed to run to waste. This comprises the distilling operation.

The next operation in the process is the carbonation of the ammoniated brine, and it is with the method of carrying out this that the name of M. Solvay is specially associated. The ammoniated brine is fed into the top of vertical towers made of cast iron rings, 5 or 6 feet in diameter, and of a total height of 50 or 60 feet. These towers are divided into compartments by iron plates, with a central hole about 6 inches in diameter; in each compartment is placed a large dish-shaped perforated "mushroom," as it is generally termed, with its convex side uppermost. Carbonic acid gas, from the lime kiln in which the lime for the distilling operation is burnt, is forced in at the bottom of the tower by means of a pumping engine, and as will be readily understood from the construction of the apparatus, is brought

into the most intimate contact with the liquor in its passage up the tower, being alternately drawn towards the centre in its passage through the holes in the plates, and distributed in each compartment by the perforated mushrooms. The carbonated liquor with the sodium bicarbonate in suspension is drawn off from time to time from the bottom of the tower, run on to filters, and the bicarbonate washed; the latter is then ready for the drying operation of which I shall speak later. The liquor, consisting chiefly of ammonium chloride, is used in the distilling operation before described. Fresh ammoniated brine is periodically introduced into the Solvay tower, so that practically the carbonating operation is a continuous one. The proportion of carbonic acid absorbed in the passage through the tower varies with the speed at which it is forced through, but I believe that the latter is so regulated that about 90 per cent. shall become available, the kiln gas, containing say about 30 per cent. carbonic acid on entering, while the escaping gas contains about 3 per cent. These latter gases are impregnated with gaseous ammonia taken up from the ammoniated brine, to arrest which they are passed through a wash-tower containing brine, which latter is employed subsequently in the absorbing apparatus connected with the still.

The sodium bicarbonate produced in this operation cannot be altogether freed from ammonia by the simple process of washing, a proportion of the latter invariably existing as ammonium bicarbonate, which is not much more soluble than the sodium bicarbonate itself.

In order to recover this ammonia, the material is heated in a suitable drying apparatus, when the sodium bicarbonate loses one of its two equivalents of carbonic acid, and the ammonium compounds are driven off in the gaseous state. The escaping gases are cooled, washed with brine to arrest the ammonia, and, when care has been taken to keep them of suitable richness in carbonic acid, are again employed in the carbonating operation. The sodium carbonate, thus freed from ammonia and excess of carbonic acid, is then ready for the finishing furnace. This, briefly described, is the Solvay system of manufacturing alkali by the ammonia-soda process. Now, in carrying out our process, we have first of all a different class of material to deal with in the distilling operation; and secondly, we have so to conduct the carbonating operation as to obtain sulphuretted hydrogen of suitable strength for the manufacture of sulphur or sulphuric acid.

To describe in detail the various steps by which we arrived at our present plan of working would occupy too much of your time this evening. We began by following tolerably closely the methods adopted by M. Solvay, but soon found that great changes were necessary. In order to make use of a vertical still it is necessary to subject the waste to some preliminary treatment. The distilling system we are now employing has not this objection, and so far has worked satisfactorily. It consists simply of four wrought-iron vessels 20 feet by 8 feet, so arranged and connected that steam can be admitted to any one of them and passed in succession through the remainder in series. A charge of ammonium chloride and waste is introduced into each vessel in turn, the system being worked on the principle of vats, so that the steam always enters the vessel containing the charge nearest being finished. The ammonium sulphide vapour, with sufficient steam to prevent the condensation of solid crystal, passes from the final vessel of the series, and is conducted through cooling pipes to a vessel in

which it mixes with brine. The cost of this distilling operation, as far as I can ascertain, corresponds very closely with that of the ordinary process; we save the labour of the preparation of the milk of lime incurred in the ordinary process; that of raising and filling in the Leblanc waste is no greater than this, but on the other hand the weight of the residue to be finally disposed of is reduced by about 45 per cent.

The condensed ammonium sulphide and brine is passed into vessels for final saturation with common salt, and after settling is ready for the carbonators. The proportion between the salt and the ammonium sulphide is carefully adjusted to a constant point, which latter will vary somewhat, as in the ordinary process, with the relative value of the materials employed; if the proportion of ammonia is increased the waste of the latter rises, while the amount of salt used per ton of ash made is reduced. The proportion we use is about 65 grms. ammonia as ammonium sulphide to 240 grms. salt per litre. If these figures be compared with the corresponding ones of ammonia and brine, it will be seen that they are weaker; this, however, is simply due to the volume being increased owing to the presence of sulphur, so that the composition of the finished liquor can be made the same in both cases.

We now come to the carbonating operation. As before explained we have to conduct this in such a manner as to obtain all the sulphur in the form of sulphuretted hydrogen of suitable richness for the manufacture of sulphur or sulphuric acid, the strength we aim at being from 30 to 35 per cent. This strength cannot be reached with a single carbonator of the Solvay design when only ordinary kiln gas is used, not only on account of some of the carbonic acid passing through unabsorbed, but owing to the formation of bicarbonate of soda being necessary, so that only one equivalent of sulphuretted hydrogen is evolved for two equivalents of carbonic acid absorbed. We found, however, that by careful working it was possible to carbonate the liquors to a considerable extent without any evolution whatever of sulphuretted hydrogen or escape of carbonic acid with the inert gases, and that subsequently sulphuretted hydrogen of a richness suitable for our purpose could be obtained. This action may be represented as, first, the conversion of two equivalents of ammonium sulphide into one equivalent of ammonium bicarbonate and one equivalent of ammonium sulphhydrate, and, secondly, the decomposition of the sulphhydrate—

In applying this principle we employ a plant consisting of nine vessels or carbonators with connexions, so that gas may be forced into any one of them, and from it through the remainder in series. Besides the outlet leading to the next vessel, each one has two other outlets into two mains connected with two washers for arresting ammonia; all these connexions can be opened and closed at pleasure. The carbonators are small Solvay towers 24 feet high, provided with plates and mushrooms. Eight carbonators are in operation at the same time in two sets of four, one set preliminary carbonating, and carrying out the action represented in the formula (a), and sending inert gases into one main, while the other set is constantly sending off sulphuretted hydrogen as shown in formula (b), kiln gas being admitted to the first carbonator of each series. The connexions are so changed in the progress of working that each carbonator, from the time it is

charged with fresh liquor to the time it is finished and ready for running off, passes through the whole of the two series, beginning with the fourth of the preliminary series, and so on to the first, and then from the fourth to the first of the final series, the first of the series in each case representing the one at which the gas enters. With this plan of working there is no occasion for any carbonator at any time to be standing idle, except for the purpose of emptying and refilling, and further we have not the disadvantages of the varying pressures that we should have on the system if we varied the number of vessels through which the gas had to pass. The change in the composition of the liquor in a carbonator due to the action of the carbonic acid as it passes through the two series may be explained by this diagram. The eight rectangular spaces represent the composition of the liquor in each vessel from the time it is first connected to the next change, that on the left being the fresh liquor, and that on the left the finished. The horizontal lines represent the lengths of equivalents. Since each tower becomes in turn the fourth, third, second, and first of the preliminary series, and then the fourth, third, second, and first of the final, we may regard the liquor as travelling from left to right. When first connected the liquor contains one equivalent of H_2S and no CO_2 ; for a time the proportion of the former increases, and then again falls until, on leaving the preliminary series, it is the same as starting. The carbonic acid entering at the first vessel practically never reaches the fourth, being almost entirely absorbed in the first and second; on the point of the change from the preliminary to the final carbonating, the proportion stands as in the case of the sulphuretted hydrogen, at one equivalent, which represents the theoretical composition of the liquor regular supplied to the final series.

This diagram represents the action of pure carbonic acid on pure ammonium sulphide. In practice the latter always contains some carbonate, and rather less than an equivalent of sulphuretted hydrogen; also, owing to the presence of inert gases with the carbonic acid, the practical maximum point of saturation is rather less than the two equivalents theoretically possible. The nine towers we have now at work with kiln gas 30 per cent. give a steady flow of sulphuretted hydrogen of 25 per cent., and are able to produce 16 to 18 tons 58 per cent. ash per 24 hours. When the kiln gas is supplemented by the strong carbonic acid from the decomposers, the sulphuretted hydrogen is proportionately stronger, and the turn-out of the towers greater. The gases on leaving the carbonators are passed through wash-towers to arrest ammonia, as before mentioned. The wash-towers we employ are divided into two compartments, each containing brine to a depth of about 6 feet, and connected so that the gases pass first through the lower one and then the upper one. The lower compartment from time to time is emptied, the liquor in the upper one run into it, and fresh brine introduced above.

The finished liquor from the carbonators with the sodium bicarbonate in suspension is run on to filters, washed with water, and dried, as far as practicable, with a vacuum pump.

The next operation is drying and decomposing this crude bicarbonate. This is done in a circular iron vessel with a flat bottom made of cast-iron plates. It is provided with powerful stirring apparatus, with scrapers so adjusted as to keep the bottom clean and free from scale, which is very apt to be formed if the bicarbonate is at all too wet. Heat is applied underneath and around the vessel.

The escaping gases and steam are drawn off by means of a pump through a cooling apparatus and washer, where the ammonia is caught. The carbonate of soda, when dry, is ready for the finishing furnace.

In the ordinary ammonia process the carbonic acid evolved in this operation, after being freed from ammonia, is generally of such strength that it may be advantageously employed again in the carbonating towers. The admission of a certain amount of air to the vessel is desirable as it facilitates the drying, so that undiluted carbonic acid is not obtained. In our process, however, any admixture of air with the gases going to the carbonators must be avoided, the result of which would be oxidation of the sulphide, and contamination of the final ash with sulphate. In order to utilise the carbonic acid from our decomposers, therefore, we are arranging to admit a certain proportion of kiln gas instead of air, and so prevent any access of oxygen.

In comparing the working of our process with that of the ordinary ammonia one, it will be seen that as far as labour is concerned we are under no disadvantage. In some particulars it may be a trifle higher, but this is compensated for by our having no milk of lime to prepare, and also by our having a reduced quantity of final residue to dispose of, as compared with ordinary Leblanc waste. The proportion of fuel must evidently be the same in all the operations but the distilling one. In this we save the steam that is required to counteract the mixing that occurs in the vertical still, to which I before referred, while more steam is required for the decomposition. The net result I believe to be about the same.

The proportion of salt used is the same in both cases, and the waste of ammonia should be no greater. This loss of ammonia is the terrible presence at the threshold with which the ammonia-alkali makers have most successfully warned off others from following. No doubt every manufacturer in starting an ammonia process, unless ably assisted by some who have already gained experience, has had to pay dearly for it; but with proper guidance and careful management, and, of course, a carefully-erected plant, no unreasonable loss should take place. The strictly chemical losses, such as the ammonia carried off by the escaping gases, and in the spent liquor from the still, can easily be checked and determined. In my experience, however, unreasonable losses have been chiefly due to accidental leakages and overflows, mainly due to carelessness and inexperience on the part of workmen. Arrangements should therefore be made to render such losses impossible, such as having efficient means for catching drippings from the pumps, taps, &c., preserving them from contact with the air, and returning them immediately to the process. The great principle to be grasped by all connected with the management of the process is that no loss of ammonia is so trifling that it may be disregarded, and when once this idea is grasped, the most ordinary intelligence will suggest means of arresting it.

In the ordinary process, the loss, I believe, corresponds to about three parts of ammonium sulphate per 100 of 58 per cent. ash.

I spoke before of the importance of preventing oxygen from coming in contact with our sulphide liquors, the result of which would be precipitation of sulphur with the sodium bicarbonate and, finally, formation of sodium sulphate in the soda ash. To prevent this we work our lime kiln so as always to have a little carbonic oxide, and can easily manage to keep the oxygen under .2 per cent. Our

stock tanks and saturators are connected, through a scrubber, with the gas holder, so that gas, and not air, shall enter them when liquor is drawn off. A little sulphate is always found in the finished ash, but with careful and regular working this can be kept down to about 0.25 per cent.

The wear and tear of plant seems to be inconsiderable; a short time ago we took down a Solvay tower that had been worked very irregularly for about 12 months. The interior surface of the rings did not show the faintest sign of any corrosive action, the sharp edge of a run-off connexion, for example, being as perfect as when fresh from the foundry; should, however, any liquor come in contact with the outer surface, oxidation of the iron takes place very rapidly. We, therefore, are particular about tarring all vessels on the outside. The action on the wrought iron in the distilling plant seems also very trifling; we have had one vessel employed steadily for about nine months, and can detect no sign of wear and tear.

We are now, therefore, in a position to clearly demonstrate to the Leblanc makers the immense value to them of this process. For years past we have had to face a ruinous competition with the ammonia-alkali makers, in which they have severely suffered; with the help of our process, however, the conditions of the struggle are entirely altered. We have an ammonia-alkali process, practically identical with the ordinary one as far as consumption of salt, fuel, and ammonia, and expenditure on labour are concerned; we have an entire saving of lime, used in the ordinary process; and we obtain the sulphur from our Leblanc waste in the form of sulphuretted hydrogen, absolutely free of cost. A simple calculation will show that by it, if we credit the alkali produced with the sulphur we can recover, and the lime we make, and allow amply for the excessive price we have now to pay for salt, this alkali can be made at a price far below what is possible by the ordinary ammonia process worked under the most favourable conditions.

I have so far only described the method of working this process in which the calcium in the alkali waste is utilised to the full extent in the distilling operation; in this case the proportion of soda ash to sulphur made seems to be about $3\frac{1}{2}$ to 1.

Under certain conditions it might be desirable to extract the sulphur from alkali waste without making alkali to such an extent as the above proportion represents. We have two alternative methods of working our process so as to accomplish this. In the first of these we preliminarily carbonate the waste itself with kiln gas, without allowing any loss of sulphur as sulphuretted hydrogen, and employ the mixture of calcium carbonate and sulphhydrate produced, or the latter alone in form of solution in the place of ordinary waste in our distilling operation.

It will be at once seen that if the carbonation of the waste is carried out so as to convert the whole of the calcium sulphide into calcium carbonate and sulphhydrate, a double yield of sulphur will be the result. Our second plan is to employ a considerable excess of waste in our distilling operation; in doing so we find that this excess parts with about 75 per cent. sulphur as sulphuretted hydrogen by the simple action of the steam under pressure.

The sulphuretted hydrogen we are converting into sulphur on the old lines of partial combustion with a limited amount of air. The gas and air in regulated proportions are introduced into the upper portion of an iron vessel containing brickwork or other heat-retaining material, and the gases below conducted

first into a brick chamber where much sulphur is deposited, and then into leaden flues where a further quantity falls in a wet and muddy state, the finally-escaping gases being passed through a wash-tower. The wet sulphur in the flues, as well as the liquid from the wash-tower, is invariably found to be mixed with thionio acids, which, of course, represents a loss of sulphur, unless some means be taken to minimise the formation of these acids, or to recover the sulphur they contain.

In order to explain how this may be done, it will be necessary for me to enter briefly into the chemistry of the subject.

If sulphurous acid and sulphuretted hydrogen be brought in contact in water, decomposition takes place, with formation of sulphur and tetra- and pentathionic acids. For a time, the sulphur is held up in the acid solution in a quasi-soluble state, but as the proportion of gases introduced to the water increases, this sulphur separates in a peculiar form, very different from ordinary precipitated sulphur, and capable of again passing into the quasi-soluble state on a further addition of water.

If to this solution a salt be added, such as sodium or calcium chloride, the sulphur at once falls as a curdy precipitate; but even this sulphur is of a peculiar modification, and to some extent capable of being redissolved in water.

If, however, the above acid solution be neutralised by an alkali, sulphur of the ordinary kind is precipitated.

The proportion of sulphur thus obtained represents only about 65 or 70 per cent. of that existing in the sulphurous acid and sulphuretted hydrogen employed, assuming the action to be arrested when the gases cease to unite with avidity. If, however, the acid solution above be subjected for a long time to the action of sulphuretted hydrogen alone, the thionio acids become decomposed, with final formation of sulphur and water. The action of sulphuretted hydrogen on sulphurous acid in presence of water may, therefore, be divided into two stages, the first rapid, with formation of sulphur and thionio acids, and the second very slow, when these acids are decomposed.

If the sulphuretted hydrogen and sulphurous acid are brought in contact in a neutral saline solution, sulphur at once falls; but thionio acids are formed to the same extent as when water alone is employed as a medium.

Thionio acids and thionates are decomposed in presence of water at a temperature of about 300° Fahr., with formation of sulphuric acid or a sulphate, sulphur, and sulphurous acid.

Now we apply these principles in the following manner: we maintain a slight excess of sulphuretted hydrogen in the gases coming from the burner, so as, in the first place, to avoid an excessive formation of thionates; the gases escaping from the leaden flues are passed through a wash-tower fed with water.

At the base of the wash-tower we admit a small quantity of sulphurous acid, produced by the combustion of a little sulphuretted hydrogen, so regulating it that the sulphur in the gases escaping from the wash-tower may be reduced to a minimum. Should the gases from the leaden flues at any time contain an excess of sulphurous acid, sulphuretted hydrogen is introduced to the wash-tower in the same manner. The water from the wash-tower we collect in a wooden tank, settle out the sulphur mud that falls, and use the clear liquor repeatedly in the wash-tower.

The sulphur mud, as well as the mud that collects in the leaden flues, we neutralise with a suitable

base, such as milk of lime, and treat it in an ordinary sulphur melter. The melting is done under steam pressure, at such a temperature that the thionates are decomposed, as before mentioned, with evolution of sulphurous acid, which gas we re-admit to a suitable point of the plant.

We are not yet in a position to speak confidently of the value of this plan of working, but all my experiments indicate that there should be no difficulty in finally recovering 90 to 95 per cent of the sulphur originally existing in the sulphuretted hydrogen in a merchantable form.

In concluding this paper, I think it only right to bear testimony to the energy and ability of a gentleman known to most of you—Mr. John Leith—whose labours both in the construction of plant and in getting the process put in operation, are beyond all praise, and can only be fully realised by those who know him.

DISCUSSION.

The CHAIRMAN (Dr. Hurter), in opening the discussion, said he was very pleased with the extremely clear and able way in which Mr. Parnell had brought forward his most interesting process for the production of alkali and sulphur by combining the ammonia-soda process with the Leblanc process. At their last meeting they had had a new process for the manufacture of alkali, of which most of them could at once see that it had not a very great future before it, and therefore he was afraid it was not very interesting to discuss the points of a process which did not seem capable of living. They had, however, a process from Mr. Parnell which was likely not only to succeed, but, according to Mr. Parnell's own estimation, ought to put manufacturers in a position better than that of either the Leblanc or the ammonia-soda manufacturer, or even of a manufacturer possessing both ammonia-soda and Leblanc soda works separately. By his process Mr. Parnell produced a certain amount of hydrochloric acid, and consequently bleaching powder as cheap as the Leblanc manufacturer did, and a certain amount of ash as cheap as the ammonia-soda manufacturer did. But, in addition to these two, he produced the sulphur for which the Leblanc manufacturer, if he meant to recover it, had to pay extra; and he saved the caustic lime which the ammonia-soda manufacturer needs for the purpose of distilling his ammonia. The paper was full of extremely interesting points, and he hoped that, considering the very important position which the process might attain some day—before long, may be—they would have a good discussion, to bring out further information, that Mr. Parnell, he was sure, would be willing to give if requested to do so. He was glad to see that the members of the Society appreciated the matter by attending so numerously. He wished they could often get so good a meeting, and that some of them would give as good a paper as Mr. Parnell's, which that gentleman had prepared in the short space of four weeks; and he hoped they would fully discuss the paper—it merited it.

Dr. S. HAMBURGER asked how the decomposition of calcium sulphide and ammonium chloride proceeded on the large scale. He had himself made many experiments in this direction, and found that it required a great deal of time to finish the operation; that is to say, however long they boiled, still some ammonium sulphide was given off. He could confirm the fact that even at common temperatures the reaction between vat waste and ammonium chloride took place, and at elevated temperatures the evolution of ammonium sulphide was steady enough. But

it appeared to him there was a difficulty to drive off all the ammonium sulphide, and this was a very serious matter as regards loss of ammonia. He must compliment the inventors on the ingenuity they had shown in devising apparatus for carbonating with dilute carbonic acid. It was, no doubt, true that pure carbonic acid was easily absorbed by an ammoniacal brine solution, but the same could not be said of kiln gases, which contained carbonic acid in a dilute state, and unless all the carbonic acid were absorbed, the sulphuretted hydrogen given off from the last vessel would contain carbonic acid, and sulphuretted hydrogen containing carbonic acid was of no value whatever. He would, therefore, be glad to hear whether the sulphuretted hydrogen contained any carbonic acid, and if so, how much per cent. As regards the mutual decomposition of sulphurous acid and sulphuretted hydrogen, they all knew that Schaffner and Helbig's process was not successful, owing to the fact that they were not able to effect this reaction with good results. The action of the two gases on each other had been investigated by Stengel and Morawski, who came to the conclusion that the formation of thionic acids was inevitable. He understood the inventors meant to avoid the formation of thionic acids as much as possible by a special mode of proceeding. He, unfortunately, did not understand the lecturer at the moment he mentioned the details. There was another point which he ought to have mentioned in discussing the first stage of the process. He always found, on boiling the vat waste with ammonium chloride, that more sulphur was distilled over than was equivalent to the ammonia, or, in other words, the vapour was a mixture of ammonium sulphide and polysulphides. He would like to hear whether the same had been noticed on the large scale, as this fact had an important bearing on the sulphur recovery. Again, looking at the process as one for the recovery of sulphur from waste, what percentage of sulphur could be obtained from the alkali waste?

Mr. E. CAREY said he was sure they had all listened with very great interest to Mr. Parnell's paper. The process was one which had been anxiously watched by the trade for some time past, and he was sure that all who had watched it had felt that the process was an extremely ingenious one, and that whatever success Mr. Parnell and his colleagues achieved in the working out of the process—a success which they all hoped they would achieve—it was a success which they most richly deserved. There were a great many points which he did not quite understand, but there were one or two about which he should ask Mr. Parnell a question. Mr. Parnell stated that in his process the waste is 45 per cent. less than the waste by the Leblanc process; he (Mr. Carey) did not see why the waste should be reduced any more than by the amount of sulphur that is taken out of it. Then Mr. Parnell also spoke towards the end of his paper upon the commercial aspect of the process, and mentioned the fact that he considered that he got his sulphuretted hydrogen for nothing. He (Mr. Carey) did not see how he got his sulphuretted hydrogen for nothing. The only source of sulphuretted hydrogen must be alkali waste, and that waste was produced from Leblanc soda, and that Leblanc soda he presumed Mr. Parnell did not make cheaper than the rest of them. Again, he should like to know if Mr. Parnell was prepared to tell them what was the actual proportion between the amount of alkali he makes by the Leblanc process and the amount he expected to make by the ammonia process. He (Mr. Carey) understood it was less than at first supposed.

Mr. HAWLICZEK, speaking on the mode of distilling adopted by Mr. Parnell in his process, said that distilling ammoniacal liquor in intermediate stages, that was to say, in vessels or stills charged and finished individually, must involve a considerably greater loss of ammonia compared with a continuous distilling operation as now practised in the well-known ammonia-soda process. The loss of ammonia in Mr. Parnell's mode of distilling, which resembled the old style of distillation in Solvay's process, would be about from 4 to 5 per cent. of sulphate of ammonia more per ton of 58 per cent. ash than in the ammonia-soda process. This loss meant an extra expense of about 8s. to 10s. per ton of 58 per cent. ash. Mr. Parnell had drawn attention to the saving of lime by the use of alkali waste without comparing the cost for the extra loss of ammonia to be debited to his process as against the saving of lime. Taking the figures as they were, a saving of 10s. for the lime per ton of 58 per cent. ash would no doubt mean a considerable gain over the present way of manufacturing alkali by the ammonia process, but this saving became immaterial if they gained on the one hand 7s. or 8s. for the lime, and lost on the other hand 8s. or 10s. worth of ammonia.

Mr. Parnell further stated that he found great difficulty in obtaining sulphuretted hydrogen of constant strength by carbonating his sulphide-ammoniated brine in Solvay towers, in consequence of which he was obliged to make extensive alterations in his former plant. The present arrangements seemed to resemble the mode and plant adopted in Chance's sulphur recovery process. But arrangements in plant which might be suited for the Chance's process might not be satisfactory for the process in question. In the alkali process, where a volatile substance, such as ammonia, was employed, the success lay more or less in the simplicity of the apparatus used, provided that the efficiency of the apparatus was the same. Mr. Parnell's system of carbonating towers seemed to complicate the process, both in plant and working, and might, with the view of obtaining strong sulphuretted hydrogen, be greatly simplified. In experiments he had carried out on a large scale with crude sulphide of sodium liquor, he had obtained a satisfactory yield of strong sulphuretted hydrogen in the Solvay towers. The sulphohydration of the mono-sulphide was at the time carried out at an intermediate stage, and this liquor then supplied in the ordinary way to the Solvay towers. To conclude, he should be obliged if Mr. Parnell would explain the first point of his question, that was with reference to the loss of ammonia due to his way of distilling the chloride of ammonium liquor.

Mr. T. GAMBLE asked whether any of the ash had been sold on the market, and how it had turned out; whether it was liked or whether there was any difficulty in getting rid of it?

Dr. HURTER said that Mr. Parnell had now been working at his process since 1886; during that time he had taken out 15 patents. That meant that he had encountered a great many difficulties, and had to find means to overcome them. At first he thought he had to use pure carbonic acid gas for the purpose of carrying out his process, and he (Dr. Hurter) should ask him how he gradually came to the conviction that the pure carbonic acid gas was not necessary? During the manufacture of that pure carbonic acid gas Mr. Parnell must have gained some experience of the behaviour of the various alkaline carbonates, and their properties of absorbing carbonic acid, and he should have been pleased to

have heard something about them. It was, of course, from a paying point of view, very important that there should not be too much ash in comparison to the chlorine products obtained, and from this point of view the remarks which Mr. Parnell made towards the latter end of his paper, that when employing an excess of waste not only is the sulphur of the waste obtained which corresponded to the equivalent of ammonium chloride introduced to the still, but also of a great proportion of that excess. Such behaviour of the waste in the still would of course enable the manufacturer to reduce very considerably the amount of ammonia-soda ash to be made in order to recover the sulphur from the alkali waste, but if the production of this additional sulphur from excess of waste introduced into the still were to be of any value, they must know whether such driving out of sulphuretted hydrogen from this excess of waste did not involve an additional loss of ammonia in the distillation; whether it did not too much prolong the operation of distillation, and whether the quantity of steam thus used was not so great as to make the sulphur not worth having? Another point of great interest was this: he understood Mr. Parnell to say that when employing lime kiln gases containing 30 per cent. of carbonic acid, he could obtain a steady flow of sulphuretted hydrogen of only 25 per cent. Now, if the principle of sulphydration were employed, and nitrogen be thrown away, he did not quite see how it was that from the 30 per cent. of carbonic acid originally employed they did not, to say the least, get back 30 per cent. hydrogen sulphide, because they ought to get more than that. There were two series of carbonators, one working into the atmosphere the other working into the gas holder; the whole of the sulphuretted hydrogen passed into the gas holder, but only half the nitrogen, therefore the strength ought to be increased. With regard to the sulphur process, Mr. Parnell had explained that he had not a chance to work it out regularly; that owing to the difficulties of the ammonia-soda process, the working had been rather interrupted, and it had not given him a chance. Nevertheless, the samples which he had brought forward were encouraging, and he thought from what he had seen done at Mr. Chance's works, Mr. Parnell would also succeed in doing. They did not hear from Mr. Chance anything about thionates, at any rate, not much, and he thought Mr. Parnell employed some similar process, so as to only burn the hydrogen and leave the sulphur. He would therefore ask, of a given quantity of sulphuretted hydrogen supplied to that kiln of his own construction, how much was really changed into these thionic acids, was it a great proportion or only a small one?

Mr. SHAPE said he understood that Mr. Simpson had some observations to make.

Mr. SIMPSON said he had merely come to listen, not to speak. The process had been a success; it gave definite advantages, as set forth by Mr. Parnell, and he thought there could be no question about that, as they obtained the sulphur from sulphuretted hydrogen as a by-product, and Chance's process recovered it as a main product. As regards the quality, they had had no complaints from customers, so he presumed it was all right. Their ash was a little less dense than ordinary ash.

Mr. LEITH said he had tried a cask the other day, and had got 1 cwt. less ash into a cask of about 17—18 cwt. than of ordinary soda ash.

Mr. E. W. PARNELL, replying, said with regard to Dr. Hamburger's question as to the facility with

which ammonium chloride could be decomposed in distillation with Leblanc waste, there was no difficulty whatever about this. The stills that he had shown might be charged and finished off in about six hours working in series, one every 1½ hours, and the residual liquor contained in 50 cubic centimetres one milligramme of NH_3 , which was pretty satisfactory working.

With regard to the presence of carbonic acid in the sulphuretted hydrogen, the escaping gas very seldom contained more than one per cent. of carbonic acid, and if it should do so they knew there was some leakage, and they looked until they found it.

The next question about the formation of polysulphides in the distillation. This must have been due (in the case that Dr. Hamburger spoke of) to partial oxidation of the Leblanc waste. A very slight oxidation would produce polysulphide, and the sulphur would produce polysulphide of ammonium.

Mr. Carey asked how sulphuretted hydrogen was to be obtained for nothing. Of course it all depended how one looked at this process. Suppose they compared it with an ammonia alkali works situated in Widnes. Such works would have to pay for salt, fuel, ammonia, limestone, and coke for their limekiln at exactly the same rates as they (the speaker and colleagues) would have to pay. They would use Leblanc alkali waste where the lime was used. The consequence was that they should have lime from their limekiln for sale, their ash for sale. They could get sulphuretted hydrogen coming off the top of the carbonators where the nitrogen would have gone into the air in the ordinary process, so that they should have sulphuretted hydrogen for nothing! They simply used their Leblanc waste in the place of lime in a process that uses lime. They got the same article, namely, soda-ash, and consequently their sulphuretted hydrogen at no cost.

The proportion of alkali that they could get was about 1 to 3 tons of alkali waste, possibly that figure would be sufficient to answer the question of the proportion of alkali made by this process against that made by the Leblanc process.

Dr. Hawliczek spoke about the loss of ammonia. In their present form of stills, with care, this was very small, not more than 0.1 ammonium sulphate per 100 parts ash made. The opening, a manhole, was perfectly tight, and they could walk round this and could not detect the faintest trace of ammonia. The run-off taps at times were apt to get leaky, but could very quickly be repacked and made tight.

Dr. Hawliczek also mentioned that he found no difficulty in getting strong sulphuretted hydrogen from sulphide solutions in the ordinary Solvay tower; probably he was not aware that this had been their ordinary method before they adopted the plan of a series of towers. They had two Solvay towers, one in which they preliminarily carbonated, and a second one in which they finally carbonated, but they found such difficulty in transferring from one to the other that they had adopted the present system as an improvement on the old.

As to the quantity of the ash they had sold, he must ask Mr. Simpson to reply to that. (Mr. SIMPSON: About 600 tons.)

As regards the amount of sulphur that was lost in the waste with careful working, he had found that the residue in the waste would contain about .5. The final residue represented about 55 per cent. of the waste originally employed. The consequence was that they had .3 per cent. against 12 per cent. in the original. Thus, when out of 12 per cent.

they extracted 11·7, which they obtained in the form of sulphide of ammonium, with good work in the towers the sulphate in the finished ash could be kept down to something like ·2 or ·3 per cent., so that the amount of the sulphur lost was very small. He thought there was no difficulty at all in getting about 95 per cent. in the form of sulphuretted hydrogen. Many of them had recently investigated to what extent sulphur could be made from sulphuretted hydrogen, and he thought that there was no question whatever about recovering 80 per cent. in a merchantable form.

Dr. HURTER asked why it was that they had abandoned the preparation of pure carbonic acid. Well, they had no difficulty in manufacturing pure carbonic acid, but, before they had perfected their plant, he found it was possible to work entirely with kiln gas in the manner described, and obtain sufficiently strong sulphuretted hydrogen without the preparation of pure carbonic acid, so they were induced to abandon it. In making pure carbonic acid he had only operated on soda solutions. He had carbonated in the ordinary Solvay tower about 65 feet high, and ran off the bicarbonate, steamed it, and returned it again for bicarbonating. The only difficulty about that method was that there was very great dilution due to the manner of steaming, which could easily be modified. As a method for producing carbonic acid cheaply enough for any manufacturing process he really thought it would be hard to beat.

With regard to the extra cost of using the excess of waste, he had never appreciated that the charges had taken longer to finish when they had a moderate excess of waste, so that he did not think that the extra cost of working with an excess could be very serious, and if they would consider the very small proportion of ammonia that could be left in this final still liquors, even if doubled or trebled it still would be very small in proportion to the total loss. The total loss which they ought not to exceed was something like 3 parts of ammonium sulphate to 100 of soda-ash. Dr. Hurter also asked about the 25 per cent. obtained; he could hardly have made himself sufficiently clear. This diagram represent the action of pure carbonic acid. With pure carbonic acid they could get the true mixture of sulphhydrate and bicarbonate. Thus they had one equivalent of carbonic acid to the one equivalent of sulphuretted hydrogen. When they preliminarily carbonated with lime kiln gas they could not reach that point. Suppose the carbonic acid only comes to ·8 equivalent and the sulphuretted hydrogen, say, 1 equivalent, the proportion on leaving the series being the same as on entering, to complete the carbonation to bicarbonate, 1·2 equivalent of carbonic acid is required, while only 1 equivalent of sulphuretted hydrogen is obtained. Consequently, only about 25 per cent. H_2S is obtained when kiln gas of 30 per cent. CO_2 is employed.

The final question was as to the proportion of sulphur they obtained in the form of thionic acids.

This was rather a difficult question for him to answer. They had been working very irregularly, and in starting they would have a large excess of sulphurous acid, while the plant would be upset again on stopping. When this had been the case they had always found that a very large amount of these thionic acids had been formed, but with regular working, as they knew, they could get down about 60 or 70 per cent. of sulphur in the ordinary reaction in the wet way from sulphurous acid and sulphuretted hydrogen. He thought that there could be no doubt that they showed a higher yield of pure

sulphur with a kiln, that is if in the wet way they got 35 per cent. sulphur as thionic acids with the ordinary methods, with the kiln they should not get more than 20 per cent.

Dr. HURTER: But in the kiln you are supposed to mix just sufficient air to burn the H_2 of the H_2S , and it is only an excess of air that may now and then produce the sulphurous acid. You produced this sulphur (of which you have two bottles here) in the kiln. Well, that sulphur must represent a given proportion of the H_2S , &c. Therefore the thionic acids cannot be that great proportion. In this case the sulphuretted hydrogen you take is in a great measure turned into sulphur and water, and only a small quantity of it is turned into sulphurous acid, and a small proportion escapes as H_2S with it. It is only on this small proportion that thionic acids are formed.

Mr. PARNELL, continuing his reply, said that was what he believed to be the case, but it certainly appeared as if, when they had the most perfect mixture possible, and passed it through the most perfect burner in existence, that at a certain stage the water and sulphur reacted on each other and again made sulphuretted hydrogen and sulphurous acid, and thionic acids. In fact, if you take sulphur and put it into a flask and boil it with water you can get sulphuretted hydrogen.

Dr. HURTER: Then, although you may write an equation $\text{H}_2\text{S} + \text{O} = \text{H}_2\text{O} + \text{S}$, in reality it does not go by that reaction, but a certain amount of sulphuretted hydrogen burns to sulphurous acid.

Mr. PARNELL: If at any time they do completely form $\text{S} + \text{H}_2\text{O}$ they again had a decomposition of the water.

DR. SCHUNCK, F.R.S., IN THE CHAIR.

I.—ON WOOL AND FUR, THEIR ORIGIN, STRUCTURE, CHEMICAL AND PHYSICAL PROPERTIES, AND COMPOSITION.

BY WATSON SMITH.

Lecturer on Chemical Technology in the Owens College.

Wool and the different kinds of fur and hair covering certain classes of animals such as sheep,

goats, rabbits, and hares, we may generally discriminate from one another in that wool differs from fur and hair, of which we may regard it as a variety, by being usually more elastic, flexible, and curly, and by possessing certain peculiarities of surface-structure conferring upon it the property of being more easily matted together than are fur and hair. Yet this attempted definition needs to be cautiously advanced, for the fact is, as Dr. Bowman, our greatest authority, observes in his work on the wool-fibre: "The difference between wool and hair is rather one of *degree* than *kind*, and all wool-bearing animals have the tendency, when their cultivation is neglected, to produce hair rather than wool. Wool and hair, fur being intermediate, are simply modifications of the same root-substance, and the scales of the wool-fibre have a much larger free margin than is the case with hair, being only attached to the stem for about one-third of their length, and in many cases the free ends are more or less turned outwards so as to present a much more serrated edge than is the case with hair. The interior portion of the fibre,

however, does not differ in the least from that of hair, and can neither be distinguished from it chemically nor microscopically."

Fig. 1 shows a section of the skin with a fibre of wool rooted in it. Here we see that the groundwork, if we may so term it, is fourfold in structure. Proceeding downwards, then, we have, 1st, the outer skin, scarf-skin or cuticle; 2nd, a second layer of skin called the *rete mucosum*, forming the epidermis; 3rd, the papillary layer; 4th, the lowest or corium layer, forming the dermis. The peculiar globular cellular masses below in the corium are termed *adipose cells*, and these throw off perspiration or moisture which is carried away by the sudoriparous glands, which pass independently off to the surface. Other glands terminate under the skin in the hair follicle, which follicle or hair socket contains or encloses the hair root. Now the complex glands referred to, terminating in the hair follicle, secrete an oily substance, which bathes and lubricates as well as nourishes the hair. As regards its origin, this hair or wool-fibre is formed inside the follicle by the

Fig. 1.

exuding therefrom of a plastic liquid or lymph, and this gradually becomes granular. It is then formed into cells, which, as the growth proceeds, become elongated into fibres, and forms at length the central portion of the hair. Just as with the trunk of a tree, we have an outside dense portion, the bark, and an inner less dense and more cellular, and then an innermost portion, which is most cellular and porous, so with a hair, the central portion is loose and porous, the outer more and more dense. Glancing at the figure (Fig. 2) of the longitudinal section of a human

Fig. 2.

hair, we observe first the outer portion like the bark of a tree, consisting of a dense outer sheath of flattened scales, then comes an inner lining of closely-packed fibrous cells, and frequently an inner well-marked central bundle of larger and rounder cells, forming a medullary axis. The transverse section shows this exceedingly well (Fig. 3). The end of a hair is generally pointed, sometimes filamentous. The lower extremity is larger than the shaft, and terminates in a conical bulb or mass of cells, forming the root (Fig. 1).

In the next figure (Fig. 4) we are supposed to have separated these cells, and above, (A), we see some of the cells separated from the central pith or medulla, and fat globules; between, (B), some of the intermediate elongated or angular cells, and below, (C), two flattened, compressed, horny scales from the outer portion of the hair. Now these latter flattened scales at the surface are of great importance to the textile manufacturer. Their character and mode of connection with the cortical substance below makes all the difference between wool and hair, and so determines the extent and degree of that peculiar property of interlocking of the hairs, known as felting (Fig. 5). We observe that the very structure described indicates the very considerable porosity of wool and fur-fibres, and their capacity for being cleansed by proper agents from all greasy and other matters between scales and pores.

Let us now look at the general external structure of a hair, say a human hair. The upper or free edges of the scales are all directed towards the end and away from the root; in fact, in the case of some of the more perfect wool fibres the appearance under the microscope is almost like that of a number of

Fig. 3.

minute cups inserted and piled up within each other. The fact of the peculiar serrated structure is easily proved by a simple mechanical test. Take a human hair, place it between finger and thumb, and gently rub it by the alternate motion of finger and thumb together. The hair will then invariably move in the direction of the root quite independently of the will of the operator.

Fig. 4.

When a hair or wool fibre is in its natural state, and hence with its pores full of natural grease and its surface more or less lubricated, it feels smooth and soft, also on looking at it through the microscope its scales are not always easily discernible as scales, but look like lines or markings. There are several ways of making this scaled surface perceptible to the touch, and the scales, as scales, perceptible and plain under the microscope. Moreover, since this development of the scaly structure is an important condition for the milling and felting processes, in which it is of equal importance that the integrity of the surface (the smoothness and polish of the scaled surface, the smoothness, too, of the edges of the scales, &c.) be preserved as much as possible, so that that final quality of the woollen or felt goods known as a good finish may be obtained in the highest possible degree—we have to inquire as to the most harmless means of attaining the one without imperilling the other. It is clear that the use of a solvent to remove the grease, oleates, and natural salts, without dissolving or corroding the fibre, is the first natural step.

In the case of wool for spinning and weaving it is the only step necessary, previous to bleaching; for, as we shall now see, the natural development of well cultivated wool is such that the scales project quite

sufficiently for this purpose, whereas in the case of fur for felt hats the fullest development and projection of the scales is necessary to encourage the intimate approach and interlocking needed for a close and hard felt (Fig. 5). This felting is simply a contraction and condensation of the looser fibres to a compact mass by reason of an ever-increased interlocking of inverted fibres, induced by processes of beating, "bumping," vibrating under pressure, &c., and the fuller projection of the scales is brought

Fig. 5.

about by treatment preferably with acids, since alkalis exert a too considerable solvent and corrosive action. I will now show you on the screen samples of the finest merino wool fibre (Figs. 8, 9 and 10), and of various specimens of fur.

There is a saying amongst felt manufacturers that "dead wool won't felt." By this I understand wool from animals that have died of disease. It is now interesting to observe how diseased wool appears under the microscope, and this I will show you on the screen. (Fig. 6.) You see there the

Fig. 6.

mystery revealed and solved. The fibres are attenuated, irregular, the scale markings and edges almost disappeared in some places, and generally scanty and meagre in development, and hence felting with such fibre must be imperfect. (See Fig. 6.) Such diseased wool is nearly as bad as

Fig. 7.

"kempy" wool, in which malformation of fibre has occurred. In such kemps, as Bowman shows, scales have disappeared and the fibre has become in part or whole a dense non-cellular structure, resisting dye-penetration and felting. (See Fig. 7.)

Let us now consider the chemical composition of wool, fur, and hair. We shall best do this by considering apart: (1) the composition of the pure

Fig. 8.

Fig. 9.

Fig. 10.

Fig. 8. Finest merino wool fibre.

Fig. 9. Wool fibre showing typical structure.

Fig. 10. Wool fibre from Chinese sheep.

fibre itself; and (2) that of the substances, fats, saline compounds, and grease, associated with it.

Pure fibre of wool has something like this composition in 100 parts: carbon = 49.25 per cent., hydrogen = 7.57 per cent., oxygen = 23.66, nitrogen = 15.86, and sulphur = 3.66 per cent.

As regards the sulphur, it is difficult to look upon this as an integral constituent of pure wool fibre, since it is removed to a greater or less degree by most solvents, and in different wools the variation has been found to be from 0.75 to 3.8 per cent.

Based on the fact of the presence of sulphur, is a method for discriminating wool fibre or fabric from those of silk or cotton.

Plumbite of soda, when boiled with wool, at once blackens it, whilst silk and cotton are not blackened.

Based on this fact, moreover, are the old methods of dyeing the hair black with lead solutions, though at the risk of introducing lead into the system, followed by colics and contractions of the limbs.

For the quantitative determination of wool in presence of silk and cellulose fibres, a useful reagent is basic zinc chloride made by dissolving 100 parts of fused zinc chloride with four parts of zinc oxide in 85 parts of water at a boiling heat until a clear solution is obtained. This solution dissolves silk slowly in the cold, quickly if hot, and forms a thick gummy liquid. Wool, fur, and vegetable fibres are not affected by it. But another solvent is required for removing wool or fur, and that is caustic soda solution, especially if hot. Vegetable fibres remain undissolved. (See this Journal 1882, 64, and 1884, 517.)

Vegetable fibres are easily removed from silk and wool by a mere soaking in dilute sulphuric acid of about 3° Tw., followed by drying. The cellulose fibres are destroyed and converted into mere dust, which can be removed by shaking or beating out the dust. In strong sulphuric acid, cotton and cellulose fibres are dissolved, especially on gently warming; wool is but little affected and certainly not dissolved; silk is at once dissolved, even in the cold. Addition of water to the cellulose and silk solutions causes only dilution of the clear liquid; but addition of tannic acid, whilst leaving the cellulose solution unaffected, precipitates in a curdy form the fibroin from the silk solution. A solution of oxide of copper in ammonia dissolves cotton and silk, but not wool, and from the cellulose solution, a solution of sugar or gum precipitates the cellulose, whilst no precipitation is effected in the solution of the silk. The following solvent finally is efficacious for silk, whilst leaving cellulose fibre and wool undissolved. Sixteen parts of copper sulphate (cryst.) are dissolved in 150 parts of water, and to the mixture are added 16 parts by weight of glycerol. The mixture is then treated with a solution of caustic soda until the precipitate first formed is just redissolved.

From these data, schemes for quantitative estimation in mixture of cellulose fibres, wool and silk, can readily be constructed.

In dyeing certain shades and colours on wool, it is sometimes necessary to remove as much of the sulphur as possible from the fibre, and Chevreul, I believe, introduced the method of steeping in milk of lime, washing with water, weak hydrochloric acid, and water again, with several repetitions of the process. Silk differs from wool, amongst many other things, in containing no sulphur, but it contains about 18 per cent. of nitrogen. Hummel gives the amount of mineral matter in wool, free from yolk, as 0.08 to 0.37 per cent. This consists chiefly of phosphates and silicates of lime, potash, iron, and magnesia.

Wool that has been fully cleansed from foreign matters has a chemical composition very similar to that of feathers or horn. The name Keratin has been given to such substances. Dr. Knecht, of Bradford, has been endeavouring to isolate from wool the substance which unites so readily with coal-tar dyes and other dyestuffs to form apparently beautiful lakes in the fibre. This substance, he argues, is a basic one, since acids and acid coal-tar colours and colour-acids are all absorbed and retained after washing. Moreover, by treatment with sulphuric acid, he has apparently removed this substance by solution. This solution he filtered and found that it forms, with most of the acid coal-tar colours, richly-coloured lakes, or precipitates. By neutralising the sulphuric acid solution with NaOH, he obtained a curdy precipitate of the substance.

But we have been speaking of the purified fibre. Let us now ask what proportion this bears to the impurities associated with it in the raw wool. With such a structure as that which we have seen wool possesses, it can be no matter of surprise if the greasy matters, natural oily substance, saline matters, &c., stowed away behind and around those numerous scaly envelopes, should amount to a very considerable proportion. Such is indeed the case. When dry sheep's wool is treated with very dilute hydrochloric acid (0.13 per cent. HCl), ether, water, and alcohol successively, and then again exhausted with alcohol and ether, all the soluble ingredients are removed and the insoluble matters left can only be separated mechanically. The ether dissolves the fat, the water the wool-sweat, principally consisting of the potassium compounds of oleic and stearic acids, &c., and the alcohol, what of the preceding the other solvents leave.

In some cases the loss thus obtained amounts to from 20 to 50 and up to 70 per cent. of the air-dried wool.

Again, another surmise may be very properly grounded on the peculiar structure of the wool fibre, viz., that such fibre is very likely to absorb moisture readily and retain it persistently. This is the case, and little attention has been paid to it in England, as Dr. Bowman and Professor Hummel point out. On the Continent a manufacturer will not buy water as wool, and official public testing establishments are situated in all the principal centres in Germany and France.

According to Bowman, the water in wool is there in two conditions: (1.) As moisture; and (2.) As water of hydration, or water really belonging to the fibre in its natural state.

He has determined the latter by drying wool at 38° C., and then exposing it to the air at from 10° to 16° C. He then found that the amount of moisture regained was about 8½ per cent. However, though mentioning that the amount of water absorbed depends on the amount in the air, Bowman does not here state the hygrometric condition of the air at the time. I understand that the condition of the atmosphere is so critically considered by practical men, that some wool staplers in Bradford will not sell after an east wind has been blowing for some days. However, the average loss at 100° C. is 14 per cent., but it is not unattended with some decomposition, and the fibre is turned yellow. This means a further loss of 5½ per cent. in addition to the 8½ per cent. This wool exposed to the air regained much of the loss, but not all, showing that injury to the fibre had commenced.

On the Continent it has been found that if exposed to a temperature verging upon that which would

cause scorching of the fibre, it will regain 18 to 18½ per cent. of the moisture.

J. Persoz finds that whilst at 130° to 140° C. wool fibre is completely disintegrated, when moistened with a 10 per cent. solution of glycerol, it remains unaffected at this temperature (Monit. Scient., July 1887).

Chevreul, after determining in wool dried at 100° C., the earthy matter, suint, and neutral fats, found that only 31½ per cent., or less than one-third, of pure textile fibre remained. Dr. E. Knecht finds a similar amount of fibre in a sample of greasy Russian wool.

Chevreul's analysis of raw merino wool, after drying at 100° C., gave him of—

	Per Cent.
Earthy matter deposited by washing the wool in water	26.06
Suint or yolk, soluble in cold distilled water	32.74
Neutral fats (soluble in ether)	8.57
Earthy matter adhering to the fat	1.40
Wool fibre	31.23
	<u>100.00</u>

Generally, it may be said, the finer qualities of wool (merino) contain more yolk ("suint") than the coarser kinds.

Now, as regards this yolk and the part it plays in the nourishment and growth of the wool, Youatt says: "The filament of the wool has scarcely pushed itself through the pore of the skin, than it has to penetrate another and singular substance, which from its adhesiveness and colour is called 'Yolk.' It is found in greatest quantity about the breast and shoulders, the very parts that produce the best, healthiest, and most abundant wool; and in proportion as it extends in any considerable degree to other parts the wool is then improved." The fineness, strength, and lustre of the fibre depends upon this natural defence, lubrication, and nourishment combined.

In a determination of the constituents or analysis of raw wool, Hummel, in his "Dyeing of the Textile Fibres," gives the following outlines:—

(a.) *Moisture* is determined by drying at 100° C. in a stream of hydrogen (inert gas).

(b.) *Wool-fat* by extraction with ether, thereby removing also the oleates, subsequently removed by shaking the ether solution with water. The ethereal solution contains the *wool-fat*, the aqueous the *oleates*.

(c.) Residual wool is repeatedly washed with cold distilled water; more oleates are thus extracted. They are mixed with those from the ether, *see* (b). The wool is then washed with alcohol. More oleates are thus extracted, and their weight is added to those from the aqueous solution. Earthy oleates left in the wool are decomposed by weak hydrochloric acid. The acid is removed by water, the wool dried and treated with ether and alcohol. On evaporating the solvents named to dryness, residues are obtained from which the amount of earthy oleates can be reckoned.

(d.) The wool is finally dried and well shaken, and teased out over paper, to remove dirt, sand, &c. When washed on a fine sieve the wool is dried and weighed, and the sand and dirt taken by difference.

Märcker and Schulz, using the method sketched above, obtained the following results:—

	Wool of Lowland Sheep.	Wool of Full-bred Rambouillet Sheep.	Pitchy Wool.
Moisture	Per Cent. 23.48	Per Cent. 12.28	Per Cent. 13.28
Wool-fat	7.17	14.66	34.19
By successive treatment:			
Soluble in water (wool sweat)	21.13	21.83	9.76
Soluble in alcohol	0.35	0.55	0.89
" in dilute HCl ..	1.15	5.64	1.39
" in ether and alcohol	0.29	0.57	..
Pure wool fibre	43.20	20.83	32.11
Dirt	2.93	23.64	8.38
	<u>100.00</u>	<u>100.00</u>	<u>100.00</u>

Wool-fat is not a compound of glycerol, and consequently is not a true fat. It is separable into two portions by treatment with boiling alcohol, the lesser soluble and the larger insoluble. The soluble part contains chiefly the at once alcohol-like and fat-like body *Cholesterin*, which is a carbinol, along with *Iso-cholesterin*, whilst the insoluble part contains principally these latter bodies combined with oleic acid, and in small quantity with stearic and other fatty acids.

So called "pitchy wool" contains much wool-fat, which is difficult to remove by scouring with mild alkalis.

A method issued by the Fab. Chem. Prod. Act. Ges., of Berlin, of separating the constituents of commercial wool-fat (C. D. Abel, Eng. Pat. 326, January 8, 1886) is based on the fact that the raw product is soluble in carbon bisulphide, benzine, benzol, xylenes, toluene, isobutyl alcohol, or amyl alcohol, but from its solution in these all the soaps (*sic*) are completely precipitated by the addition of acetone. The fatty acids of commercial wool-fat can be separated from the wool-fat by converting them into alkali soaps by adding alkalis, and then treating the whole with ethyl or methyl alcohol. With the aid of heat all is dissolved, but on cooling the wool-fat separates, leaving the soaps in solution. The easiest plan is to treat the raw wool-fat with ammonia and then with alcohol. The ammonia soaps dissolve and leave the wool-fat, which, after emulsifying with water, forms "*lanolin*." (*See this Journal* 1886, 579.)

A more recent method by Langbeek and Ritsert (Eng. Pat. 6210, May 7, 1886) is to treat raw wool-fat, freed from water and dirt, with boiling alcohol containing about 10 per cent. of ether, the warm alcoholic solution of the free fatty acids, free cholesterin and iso-cholesterin and volatile ethers of the fatty acids containing also a small quantity of cholesterin fats are separated from the undissolved cholesterin fats. The alcohol is removed and the cholesterin fats distilled off by superheated steam. Another way was to dissolve the whole wool-fat in ether and precipitate the cholesterin fats alone by addition of alcohol. This method is applicable direct to the lyes from wool-washing works.

I understand in these methods that raw wool fats which have been already separated from other matters are taken, but I also think the fact called attention to by Hummel, p. 92 of his "Dyeing of Textile Fibres," has been much overlooked by

chemists and inventors too, viz., that soaps (oleates) are not perceptibly soluble in the volatile agents proposed, CS_2 , ether, and petroleum spirit, &c., but only bodies of the nature of fats. Hence washing with water must always follow.

Wool Suint.—The portion soluble in water has been shown by Chevreul, Vanquelin, Hartmann, &c. to contain principally the potassium salts of oleic, stearic, hyenic, and other fatty acids, along with others in smaller quantity of potassium with valerianic and acetic acids, and also phosphates, sulphates, chloride of potassium, &c. Ammonium salts are, moreover, present in small quantity.

It is not necessary to call attention to the great value of the constituents of the suint and salts. 1st. As regards the potash. 2nd. The possibility of making ferro- and ferricyanides from them. 3rd. As a source of lanolin and cholesterin—for this has already been done in papers published in this Journal by Ivan Levinstein, 1886, 578–580, and W. Bott, 1883, 123–124. Hummel also gives a useful account of it in his *Dyeing of Textile Fibres*, pp. 40–43.

Quite recently (*Compt. Rend.* 107 (20), 789–792) A. and F. Buisine have discovered in suint, and isolated from it, glycollic acid and normal pyrotartaric acid, $\text{COOH} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{COOH}$ (normal propylene dicarbonic acid) a higher homologue of succinic acid ($\text{COOH} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{COOH}$). They are contained in the portion of suint soluble in water. These savants have already isolated benzoic, succinic, and malic acids. The following list of acids is given as derived from fermented suint:—The fatty acids from acetic to capric; the hydroxy acids of the foregoing; glycollic and lactic acid, and their acid amides; glycolic, leucin; the bibasic acids, oxalic, succinic, and normal pyrotartaric; a hydroxy acid of one of the preceding bibasic acids; malic acid; with some others as hippuric, benzoic, and uric, &c. These acids exist principally as potash salts.

Acetic acid amounts to 60 per cent. of all the other acids present, and Buisine hopes to recover it industrially. In northern France alone 1,000,000 kilos. should be obtained annually. (*This Journal*, 1888, 220.)

Action of Acids.—Dilute acids have little effect on wool, i.e., sulphuric and hydrochloric acids, whether hot or cold. The scales on the fibre are, however, opened out, and hence felting promoted. The feel also becomes harsher; harshness of feel is often alleged as a criterion of damage to the fibre, but it may not be so at all, for if you cleanse the fibre with CS_2 , or benzol, perfectly, and then with cold water, you get a certain degree of harsh feel simply because the oils and fats are completely removed from the surface of the fibre, and the scale-edges become more sharply developed. A microscopic examination, however, clearly shows when serious modification of the fibre has taken place.

Furriers use as a stimulant to the fibre-scales acid solution of mercuric nitrate, but they often use it so strong that the fur is stained yellow and made excessively harsh. In such cases it is undoubtedly injured, and no good finish can be got upon felt made from such fur. Figs. 11 and 12 respectively illustrate fur fibres from different parts of the same animal (hare) before and after the treatment described. The figures, of course, represent the microscopic appearances.

Cellulose is, of course, very sensitive to sulphuric acid, which disintegrates it. The felt manufacturer removes cellulose particles or burrs from his felt by steeping in dilute sulphuric acid, drying, and then beating out the dust of the disintegrated and partially carbonised cellulose. Nitric acid is also used for

Fig. 11.

Fig. 12.

stripping wool of its colour previous to redyeing. Thus indigo-dyed wool may be "stripped" with nitric acid of 3°–4 Tw. Sulphurous acid is the best bleaching agent for wool, removing its natural yellow colour. Dr. Knecht has shown that when boiled with dilute sulphuric acid, wool absorbs from 2 to 3 per cent. SO_2 , which are only removed by long continued boiling with renewed quantities of distilled water; part is removed as ammonium salt.

Action of Alkalis.—Alkalis, which have little effect on cotton, have to be used very dilute and with great caution on wool. Alkaline carbonates in solution and dilute, also at a temperature not above 50° C., have little action on wool. Soap and carbonate of ammonia have less injurious action still. If a soda ash with causticity in it be used the damage is certain. The temperature of any solution used in the case of wool is an important matter, for even hot water is injurious. Dr. Bowman finds that "wool which looked bright when well washed with tepid water became duller when kept in the water some time at a temperature of 71° C., and the same wool, subjected to boiling water at 100° C., became quite dull and lustreless." "When the water at 71° contains only very small quantities indeed of

alkali," adds Bowman, "the whole of the surface of the wool, and indeed its substance, is dissolved into a jelly-like mass." Dr. Knecht finds that wool will dissolve in a solution containing less than 5 per cent. of its weight of NaOH at boiling temperature. I have here micro-sketches of a human hair before and after treating with warm dilute alkali (Figs. 13 and 14). You will observe the projecting and jagged edges of the scales (Fig. 14) indicating corrosion and injury. The same fibres that carried before boiling

Fig. 13.

Fig. 14.

Before treatment with alkali.

After the treatment.

with water alone, 500 grains without breaking, broke after boiling with 180 grains.

In the drying of wool in chambers in the carbonising process, 121° C. may be used provided the vapours escape, for the rapid evaporation cools the wool, heat becoming latent in the steam at the expense of the fibre.

We see then that pitchy wools and rich merinos richest, respectively, in wool-fat and yolk, *i.e.*, the very finest wools, will be those needing most care in scouring with alkalis or soaps. Yet they are just the wools requiring most and strongest treatment to rid them of the extraneous matters of the yolk. Thus manufacturers have looked about for other scouring agents.

Carbon Bisulphide.—Amongst them are what are termed the *volatile scouring agents*, such as carbon bisulphide, fusel oil, ether, petroleum spirit, benzol, &c. However, these volatile bodies are solvents for fatty matters, and not for alkaline oleates and soaps. Hence, in conjunction with them, a washing with water must be combined, so as to follow the treatment with volatile liquid.

Bisulphide of carbon has, so far, amongst these agents received the most favour, as it so very readily dissolves the wool-fat, even in the cold.

Bowman says: "Bisulphide of carbon dissolves the suint and fat of wool very easily and completely, without injury to the fibre. The bisulphide may then, when removed from the wool, be driven off at a steam heat, leaving the unchanged fats behind as a residue." However, lime soaps are not removed, and it is a fact that bisulphide of carbon, if hot,

leaves the wool yellow, and bleaching will not remove that yellow colour, for it is due to sulphur deposited in the fibre.

Hummel (p. 101, "Dyeing of Textile Fibres") says the use of volatile liquids has not yet met with much acceptance, but that the difficulties attending their use have been more or less overcome by Da Heyl, Van Haecht, and others, more especially by T. J. Mullings, yet the process of the latter, who employs throughout a low temperature, is not an unqualified success. A friend of mine who has witnessed and inspected it in operation, tells me that the water run off into the river after the washing which followed the CS₂ treatment had a dreadful odour, and made the river smell for some distance. However, if properly purified by rectification from half-slaked quicklime in powder, it has little or no odour.

Benzol and petroleum spirit have the serious objections that they are specifically lighter than water, and so can neither be so easily displaced by water from the fibre, nor be sealed by a layer of water kept above their surface. Combined with this great mechanical and statical advantage of CS₂, we have the additional one of its volatility, though this, as we shall shortly see, is by no means an advantage under some circumstances.

I have in this paper endeavoured to explain the physical and chemical structure and properties of wool fibre and its natural accompaniments, so as to prepare the way for the consideration in the next of the advantages of a rational treatment of the raw wool with a volatile and inert solvent in the cold, along and alternately with water, over the treatment at present in vogue with warm dilute alkalis in the process known as scouring, and I hope to be able to prove to you that a new process just invented and patented by my friends, Messrs. Singer and Judell, fulfils all the demands made by such a rational treatment. The apparatus for this new process is now being constructed by Messrs. Mather and Platt, of this city.

II.—ON WOOL AND FUR, MODES OF CLEANSING THEM FOR THE TEXTILE INDUSTRY, AND ON A NEW PROCESS RECENTLY PATENTED BY MESSRS. SINGER AND JUDELL.

WHEN we remember how that the raw wool fibre is penetrated, encrusted, and varnished as it were with yolk and natural grease and soap-like bodies, as well as occasional actual potash soaps, and that woollen cloth and yarn contain oil (as much as 4 to 5 per cent.), and that such greasy matters repel and resist aqueous solutions like those of dyestuffs, the reason for and necessity of scouring processes will be evident.

Scouring, then, is the process of preparation in which the removal of greasy matters, natural or artificial, is involved. For many years, and from the earliest times, stale urine was used for the wool-scouring process, but more recently it has been replaced by such solvents as ammonia, sodium carbonate in different forms, soaps, and so forth. Stale urine is an unhealthy and nauseous detergent to use, ammonium carbonate is expensive, with soaps there comes the difficulty that soft waters must be used,

or else lime or magnesia soaps will be precipitated in the fibre. Liquor ammonia, used, of course, after dilution, is not without risk, for with wools or woollen goods of light colour spots or stains may be caused when the ammonia is prepared from gas-waters. The liquor ammonia ought to have been made from good sulphate of ammonia. The question will be asked, "Whence do these grey stains arise?" Doubtless from small quantities of aniline or pyridine bases that have been volatilised and driven over with the ammonia. Before using such ammonias, they should be tested (1) by Kupferschläger's method—pouring some of the liquor ammonia into a test tube containing some colourless nitric acid diluted with one-fourth its volume of water, partially saturating with ammonia, and observing if a red colour is produced; (2) by Ost's method of nearly neutralising the ammonia with acid, and noticing if an odour of pyridine is perceptible.

Now as to the use of sodium carbonates for wool scouring. Some beautiful as well as cheap salts have been offered and adopted, such as the crystallised sesqui-carbonate of Brunner, Mond, and Co., and the crystal carbonate of Messrs. Gaskell, Deacon, and Co. The first has the formula $\text{Na}_2\text{CO}_3 \cdot \text{NaHCO}_3 + 2 \text{H}_2\text{O}$, the second $\text{Na}_2\text{CO}_3 + \text{H}_2\text{O}$. With magnesian or calcareous waters the earthy carbonates are precipitated on the wool, but are more easily removed by far than earthy alkaline soaps; however, in very greasy wools there may still be risk of deposit of the alkaline earthy soaps. But there is this difficulty with alkalis. Causticity must be avoided altogether, and the carbonates be used very dilute, or the integrity of the fibre is injured. In the first part of my paper it was pointed out that the very finest wools, the merinos and pithy wools, are just the ones richest in yolk or wool-fat. These need proportionately more stress of alkaline treatment to clean them, and there comes the danger. Thus, the finest wools would encounter the most peril. However, in cases where mild alkaline treatment can be adopted, no forms of alkali can be safer than the two products named.

We now approach another method, the one more specially interesting to us on this occasion, that of scouring with volatile liquids inert to the fibre. It possesses the essential advantage over the alkaline processes that the wool may be deprived completely of its wool-fat without injury to the fibre. However, with all these methods, as so far employed, there are serious objections, either on the score of cost through loss of volatile agent, of modification of the fibre through the manner or under the condition in which the volatile solvent is employed, and through the danger attending the necessity in some stage of the process either for treatment of the fibre or recovery of the spent volatile scouring agent, of the handling of the spent product by workpeople. However, I submit that difficulty and danger are no words to frighten or deter any British manufacturer or workman, when once it is granted that superior results are to be obtained by the use of given means and instruments. Look at our houses furnished with an illuminating agent—coal gas, which, notwithstanding its purification, if let accidentally escape into our bedrooms, would certainly asphyxiate or poison us, and as if that were not sufficient, convert the atmosphere of our rooms into a dangerous explosive to boot. Note also the fact that the immense volumes of coal gas supplied to our cities are safely collected and stored in capacious vessels of wrought boiler-plate, just as the laboratory student collects and preserves his oxygen or hydrogen in the pneumatic trough under an inverted bottle or tumbler.

Do not imagine that I would palliate for a moment any admission of the vapours of bisulphide of carbon, for example, into the atmosphere of sheds or factories or anywhere where they could be breathed by work-people. I know and have specially studied the poisonous action of carbon bisulphide vapours, and I say that slow poisoning by this agent is simply a terrible thing, involving loss of mind and disease of body combined. But I do not hesitate to say that if a method is offered in which the carbon bisulphide is treated as plant, is to act in the cold, is continually recovered and automatically returned; if it is one in which there is no removal of the fetid oil-charged material from the apparatus in which it becomes oil- and grease-charged, and if whilst, in a word, the products are discharged at their proper places, the bisulphide simply circulates—then I would on these *prima facie* grounds throw in my adherence to such a method till I heard worse of it.

Let us see what has been done so far with bisulphide of carbon. Several methods have been proposed, and one of the best of recent date is by T. J. Mullings. The wool is placed in a covered-in centrifugal machine and submitted there to the cleansing action of the bisulphide in the cold. When once saturated with the yolk constituents soluble in CS_2 , the machine is revolved to extract the chief bulk of it, and the remainder left in the fibre is expelled by water admitted into the apparatus. Water being both lighter than and non-miscible with bisulphide, displaces the latter, which sinks to the bottom of the vessel. The action proceeding in the cold, Mullings claims, and rightly so, that the wool does not acquire the yellow tint invariably assumed when heat is used.

The mixture of bisulphide and water is collected in a tank, and, after settling, the former is run off below, and recovered, by distillation, for using again. Hummel, who refers to the process in his "Dyeing of Textile Fibre," says: "It has been recently tried on a large scale, with a certain degree of success."

Now let us glance at a weak point or two in such a process as this. (1.) In centrifugating the wool from the bisulphide containing these yolk constituents which are dissolved, a time will come when the wool, with a minute quantity, but probably still some, bisulphide left in it, must be exposed, in order to withdraw it, for the admission of water will not remove absolutely all bisulphide. (2.) Since the washing with bisulphide is not by a cumulative system, the bisulphide drawn off for redistilling will not be fully charged with yolk constituents. (3.) Either the dirt and insoluble matters remain amongst the wool, or are driven out amongst the bisulphide, or both conditions obtain; this would, in any case, soon necessitate a cleaning out of the centrifugal apparatus, and would increase thus danger and expense.

A modification of Deiss's apparatus for extracting oils from seeds has been proposed. It is a macerating apparatus, in which the wool is treated with warm vapours of bisulphide of carbon. The apparatus is ingenious, but it labours under this disadvantage, that the washing and treatment are not cumulative. Thus the bisulphide in the bulk will not become saturated, and so a proportionately larger volume of this volatile agent must be used for keeping in circulation, per given quantity of wool, than would be the case if a cumulative system were employed.

The annexed figure (Fig. A) represents Deiss's apparatus, which is very much used on the Continent. A store-vessel contains the bisulphide of carbon (covered with a layer of water), and also acts as receiver for the bisulphide when recovered by

distillation from the oil and bisulphide mixture which has reached the retort. By means of a pump, the bisulphide is raised to the macerator, where it comes in contact with the seeds or other materials from which oils are to be extracted. Here it is heated in contact with the seeds or other matters by a dry-steam coil, the bisulphide vapours evolved being caught and condensed in the worm, and so returned to stock in the well. When the extraction is ended, the seeds, &c. remain on the false bottom of the extractor or macerator, whilst the oil-laden bisulphide is passed over to the retort by the pipe shown at the upper part of the extractor, where the specifically lightest layer, that richest in oil, is. In the retort it is heated by closed steam, bisulphide returned to stock, and oil remaining in the retort, to be afterwards drawn off. When the bisulphide of the first treatment is run to the retort, the seeds and macerator must receive a final treatment, resulting in a dilute solution, which must then be treated in the retort.

Not only Deiss's modified apparatus, but many others proposed, suffer from this defect, the force of which you will easily recognise when I compare it, as to its result, to the lixiviation of a quantity of black ash or crude soda, all in one and the same black-ash vat. It would mean non-saturation, a lot of weak liquors, larger consumption of fuel, increased labour.

In many of the processes proposed, a great difficulty again has been the putting in of a charge of wool to an apparatus which must be opened for the purpose, and the withdrawal after washing, which is likely to be just as disagreeable and dangerous.

Not the least of the difficulties is the treatment of the dirt and sand separated from the wool, and containing, at least, some little of the bisulphide. And now, last and not least—and I speak as an old manufacturer of carbon bisulphide—the difficulty of distilling the bisulphide from the oil completely and securely, and moreover of separating, as in the case of Mullings' apparatus, the oily bisulphide from the water with which it is mixed, to do all this safely and without loss, which would mean danger even if but a very modest loss, involves the solution of practical problems of no ordinary magnitude.

I think we now see that if an effective and safe apparatus is to be put into the hands of the wool-scourer, it must in working fulfil conditions something like the following:—It must consume as little bisulphide per given quantity of wool as possible, *i.e.*, it must return nothing but a bisulphide as nearly saturated with yolk constituents as possible. The saturated solvent must proceed direct and covered to the still for regenerating from it the CS_2 , and that carbon bisulphide must be condensed and pass again direct into the washing system. The still must be one that can work automatically, like the rest of the apparatus, and work safely. It must deliver the oil, free from bisulphide, continuously and automatically as it is produced. Hence, and in other words, the carbon bisulphide must circulate through and around the entire system, including the *recovery still*, and drop the oil, so to say, on its way, and at its proper place.

But to this end the very dirt and sand deposited from the wool in the apparatus must also be automatically gathered up, and what is more, it must be as automatically washed with bisulphide (fresh) and then be rid of all traces of carbon bisulphide, which must be returned to circulation in the system, whilst the dirt and sand are automatically and continuously delivered at a specific and proper place.

The washing with water should take place in the same apparatus, and the washing should also admit of the same continuous and cumulative action as with the bisulphide. If possible raw wool must be delivered into such apparatus at one place by some simple process that workmen will easily understand, and the thoroughly washed wool must emerge at another, just as simply as the oil and grease are, and also the dirt and sand. Finally, no direct fire must be necessary anywhere near this apparatus, which may consequently be to a considerable extent isolated.

I shall now describe such an apparatus to you, and it is the one we are assembled to-night to hear about, and recently patented by Messrs. Singer and Judell, of Adelaide. It gives me pleasure to add that Mr. Ignatius Singer is also present, and will be able to answer any questions that I may fail to reply to. It is somewhat singular that seven months ago, being asked by a large woollen firm in Yorkshire to commend to them a good wool-scouring process, and looking through a number of patents, I was at once struck by Singer & Judell's patent, No. 13,699, of October 10, 1887, recommended it, and then advised the London patent agent to write to Adelaide and invite the patentees either to come or send a representative. However, these gentlemen had also been smitten with the idea that they ought to visit the mother-country, and so the letter must have reached Adelaide a day or two after they had set sail. In coming they have brought improvements on the specification referred to of an important character. Let us now examine their apparatus and process, and see if it fulfils the conditions prefigured in the ideal structure already sketched.

The raw wool is first deposited on an endless belt made of wire gauze (Fig. B, also Fig. C, *f*), down upon which comes another belt, forming an upper cover, to hold down the wool just as the belt enters the apparatus, which is a structure of iron, measuring, for an output of 50 to 60 bales per 24 hours, about 35 feet long. All lids, covers, &c. are securely luted in water. It will be observed that the top belt, as the washed wool emerges, becomes the bottom belt bearing the fresh charge of raw wool as the double belt re-enters the apparatus. The double belt, bearing the raw wool clasped in it, now descends into the first of a series of cells or cisterns, which, when the apparatus is in work is empty, when out of work is filled with water to lute the edge of the cover of the apparatus dipping into it (Fig. C). Passing into this first cell the belt passes over a roller, under another at the lower part of the cell, and then rises under the cover-lid and passes between two squeezing rollers. The band with its wool now descends into the first carbon bisulphide vessel (Fig. B. and also Fig. C), and emerging is squeezed between nipping rollers just before entering the second cell. Thus, it travels through and is washed and squeezed in 14 cells containing carbon bisulphide, when it enters five similar but deeper tanks containing water alone, in which it is also washed and squeezed (Fig. B.). The band with wool now ascends to a drying-chamber, and in its upward course is supported and run upon two rollers. In this chamber it passes upwards and downwards over hollow rollers, heated internally with steam, and it is also squeezed between the hot rollers. At length the band emerges bearing washed and dried wool. The top band now departs horizontally to a more distant roller before descending, the lower one bearing the wool passing over one nearer at hand descends sooner and lets the wool fall into a suitable receptacle or shoot, and turning around another

Fig. A.

roller lower down re-enters the apparatus as top band to that band which previously separated, and now re-laden with fresh raw wool, re-enters as bottom band (Figs. B. and C., *f*).

We have thus followed the mere course of the wool and observed that this is characterised by a continuous automatic action. Let us now follow the course of the gaseous currents, for what must immediately strike the imagination is the fact that the first cell is open, and the lid of the apparatus dipping into it is not luted when operating (only luted in water during quiescence of the machinery). Carrying the eye to the drying-chamber above, a pipe wide in its upper part and communicating with a cylindrical worm condenser, is noticed. In that wide pipe a draught is created by the aspirating action of a fine water jet or spray under pressure at *h* (Fig. B.). This draught, however, is but a gentle one, something like that produced in a vitriol chamber system. It is just sufficient to prevent carbon bisulphide vapours from receding and passing under the lid or cover dipping into the empty tank or cell into which the wool-band first enters. It is also sufficient to carry the vapours of bisulphide from the drying-chamber to the condensing worm, where those vapours are condensed and so recovered, and returned to the system. The connexion between the atmosphere of the bisulphide cells and the drying-chamber is by means of a draught-pipe furnished with a tap *e* shown in Fig. B. We notice then the general motion of the atmosphere of the system is in a direction from the entrance of the wire-band, with the same and towards the water-jet and condenser. All carbon bisulphide vapours in the entire system then tend towards and pass down the condensing worm, then returning to the "dividing-eistern," dividing bisulphide from water *d*, Fig. B. Let us now see what becomes of the dirt deposited from the wool. So soon as the carbon bisulphide dissolves out the wool grease, &c. the dirt at once falls out of the wool and sinks to the bottom of the vessel. I will show you how this takes place by a small experiment in a stoppered funnel, in which I have placed some raw wool. I pour in some carbon bisulphide, and whilst this liquid is effecting solution, you may perceive the dirt dropping out of the wool. Now through each of the first six bisulphide cells or tanks (see Fig. C. and also Fig D.), works an endless chain of perforated dredgers. The bottoms or dirt of the cells are thus continuously dredged up, the oily bisulphide draining back into the cells during the upward motion of the little dredging-buckets. These buckets just on their descent and consequent reversal, empty their contents into a gutter of semi-circular section *h*, Fig. D., through which an endless-screw agitator works (see Fig. C., *e*, *e*). The screw works the dirt and sand containing still some oily bisulphide, in a slightly upward direction along this gutter, and meanwhile an isolated dredging system, precisely similar to the six already mentioned, only that it is furnished with non-perforated buckets, and which is fixed to the tenth bisulphide cell, brings up continually a fairly pure bisulphide and empties it into the gutter with sand, dirt, and still some oil (see Fig. B.). The bisulphide runs along by its own gravity back towards the first cell, and in a contrary direction to that of the motion of the sand and dirt, which it continually washes. The washings continually flow into the first tank, which contains the most contaminated or highly charged bisulphide. The washed sand and dirt pushed on by the screw at length enter a down pipe (Fig. B. and also Fig. D., *h*) where they drop into a retort (not visible in the drawings) connected with a

Liebig's condenser. They are subjected to heat in this retort, when the bisulphide passes over and is condensed and returned into the delivery main along with the other supplies of bisulphide at *c*, Fig. B. The retort consists of a long pipe in which works an endless screw. This retort is double steam-jacketed, and the end is connected with an aspirator to draw off the CS₂. The sand and dirt drop out at the end. But let us further follow the course of the vapours to the point of their recovery. I have said that not a steam-jet but a water spray-jet creates the suction or draught carrying the vapours into the worm (*h*, Fig. B.) which commences, according to strictly scientific principles, wide, and gradually tapers down as cooling and condensation proceed. The condensed liquid falls from the worm into a small collecting space, runs by a pipe to the bisulphide main *c*, Fig. B., where it joins the stream coming from the recovery-still to be afterwards described. The bisulphide then falls into the cell or tank at the end of the tank-system, where it settles down as a lower layer under water. The air draughted through the system escapes by the central vertical pipe fixed above the collecting space in which the worm terminates. The minute quantity of bisulphide escaping with the air, it is not considered worth while to collect. The top of this shaft is fitted with a cover-valve which is closed when the apparatus is not working.

Let us now see how the carbon bisulphide is distributed and the water disposed of in the last tank receiving the recovered solvent. The overflow siphon-tube for the bisulphide is one which every tar distiller is accustomed to for separating the bottom water layer in his receivers from the supernatant one of naphtha (Fig. E.). However in such cases the lower layer, the water, is valueless, and is run off to waste, but in our present case the lower layer is the one of principal value. We need, then, an automatic arrangement for preventing the level of the CS₂ from rising above a certain point, or we shall incur the risk of getting bisulphide returned in the upper, the water overflow. Messrs. Singer and Judell have adapted a highly ingenious arrangement for this purpose, so that it is quite impossible for the level of carbon bisulphide- and water-layers to be other than constant. The carbon bisulphide overflows into and supplies the bisulphide tank nearest to the water-tank system, and the water overflows into the water tank next to the receiving or dividing tank with automatic contrivance. This automatic contrivance consists of a float (see Fig. E. and also Fig. B., *d*) which sinks in the water of the receiving tank but floats upon the carbon bisulphide. Through it, above and below, passes a slender rod with swivel joint at either end, connected with the terminals of two levers, whose opposite ends are armed with stoppers closing or opening respectively the water and bisulphide overflows, above and below. It is now manifest that when adjusted for a particular level of bisulphide in the "divider," if that level rose the float must rise, would raise the ends of the two levers connected with its axial-rod, and these levers acting on their fulcrums would respectively close up the water overflow pipe and open the bisulphide overflow siphon (which delivers bisulphide to the bisulphide tanks just as water is siphoned over from a tar-distiller's "divider"). Thus, a compensating automatic adjustment is secured, and, in principle, it is closely analogous to the float adjustment for regulating the steam pressure, and consequently the temperature, in distilling benzene and toluene, &c., in the Savalle's diphlegmating column. The water

and bisulphide then respectively overflow into the neighbouring tanks for these liquids, and so move in a direction opposite to that in which the double perforated belts with wool are travelling. Hence wool that has become cleaner always meets with a current of bisulphide that is purer still. The same thing is true of the water.

Let us now follow the bisulphide in its course. This overflows from tank to tank till it reaches the first cistern, when, flowing underneath the inner cell holding the band and rollers and passing through a fine strainer of wire gauze (*q*, Fig. C.) it enters through the exit pipe, furnished with regulating tap (Fig. B), and is slowly fed into the retort, of special construction (Fig. F). The interior is so arranged that the oily bisulphide flows down grooved sloping plates, along the bottom of the grooves of which a steam pipe is laid. The oil, free from bisulphide, at length reaches the bottom of the series of plates or trays in the retort, when it collects in the little cistern and overflows by the siphon pipe, as shown in Fig. F. At the sharp, almost angular curve made where one groove joins the next on a sloping tray, the steam-pipe, to prevent obstruction of the flow of oil, making a small arch or bridge, enters the next groove lower down and again lies along the bottom of it. These small arches are shown at *a, a*, Fig. F.

Allow me now to point to two or three apparently trivial devices in chemical engineering which, nevertheless, are calculated to astonish us by the important results achieved by them. Notice first (Fig. B. and also Fig. C.) the sloping summits of the respective inner and outer false sides of the carbon

bisulphide tanks. It will be observed that the slopes increase the depth of the tanks, whilst they guide and drain the expressed liquors from the rollers down again into the proper tanks, so that those tanks containing purer bisulphide are not contaminated by bisulphide drainings from a less pure tank nearer to the final and most highly charged tank. Besides this, by increasing the depth of the tanks in the manner described, an opportunity is afforded for the most highly charged bisulphide in each tank, which is consequently of *lowest* specific gravity, to overflow into the neighbouring tank in the most economically advantageous way, viz., at the top, and with the same advantage, to enter that neighbouring tank at the bottom. In the case of the water tanks, a similar arrangement is devised, but since the water most highly charged with saline matters, &c. will possess the highest specific gravity, and so lie nearest the bottoms of the tanks, the overflow takes place from the bottom of one tank and by the top of the next one into which the liquor runs over. This is made plain in the Fig. B.

This is not an apparatus that has been merely worked out on paper. It has been very carefully operated in Australia for some time by the inventors, and I am assured that in the neighbourhood of the scouring plant no smell whatever of carbon bisulphide can be detected when the apparatus is in full work.

A patent has still more recently been taken out by G. and A. Burnell, of Adelaide, for a very similar piece of apparatus to that of Messrs. Singer and Judell, but it is one in which it is proposed to use benzine or petroleum spirit.

In using petroleum spirit, a rectification would first be needed to free the ordinary spirit of the trade from the partly greasy, partly resinous bodies of higher boiling point which it always contains. I miss in Burnell's specification any account of a continuous distilling apparatus to restore fresh solvent and give a continual supply of oil, and I fear for the security of the leather-lip arrangement to "prevent as much as possible the escape of the fumes."

Messrs. Singer and Judell calculate that the profits derived from the by-products of their process (the wool fats and potash salts, &c.) should pay the whole expense of royalties, apparatus, and bisulphide required.

In conclusion, my best thanks are due to Dr. F. H. Bowman for kindly lending me his lantern slides for the illustration of my papers, and for permitting me to reproduce some of the wood-cuts from his well-known work on the wool fibre, also to Mr. Ig. Singer for drawings of his apparatus and for other assistance in preparing this paper.

MR. T. W. STUART IN THE CHAIR.

ON THE TESTING OF LARD FOR COTTON-SEED OIL AND BEEF STEARIN.

BY JOHN PATTINSON, F.I.C.

As much attention has recently been drawn to the prevalence of lard adulteration, I thought it would interest some of our members if I described briefly some of the methods by which these adulterations are detected and measured.

Although chemists have only lately been able to speak with certainty as to these adulterations, it has for some years been well known that lard, which ought to consist only of the fat of the pig, is very largely adulterated with cotton-seed oil and beef stearin, and occasionally with water. Some of the

American lard packers are the greatest offenders in this respect; but they are not the only offenders, for well authenticated cases are known in which both English and Irish prepared lards have been found to contain similar adulterations.

The lard trade of America has assumed very large proportions. It was stated in evidence before a Commission recently appointed by the United States House of Representatives to inquire into the question of lard adulteration, that about 270,000 tons are annually produced in America, upwards of one-half of which is exported to other countries. Amongst the American lard packers there are several who prepare and supply only pure lard, but it was stated before the same Commission by one of the largest producers that three-fourths of the American lard was packed by his firm and a few other large firms, and that these firms, "in order to keep up the quality and to meet the demands of the trade, added cotton-seed oil and oleomargarine stearin" to their lard. This lard is all branded and sold as "Refined Lard," "Pure Refined Lard," and other names calculated to lead the purchasers to believe that the lard is genuine pure lard. The cool way in which this perversion of the ordinary meaning of the word "Refined" is defended is amusing. To the question, "Do you think that if there was only 20 per cent. of lard in your compound, it would be right to brand that as refined lard?" the same witness answered, "Yes, sir. After we have been putting up lard for 25 years we claim to become expert in the manufacture of an edible lard for domestic purposes. If we consider that we can make an article that meets the demand of our trade, fulfils the wants of the trade, and is pure and wholesome and valuable, and can put in 50 or 60 per cent. of cotton-seed oil and harden it with 20 per cent. of lard (beef stearin?) to make it firm, it meets the demand of our trade. That is all they want. We know what they want better than they do themselves."

* * * * If we choose to say we are willing to put in our brand of refined lard only about 20 per cent of lard, we consider it perfectly fair to do it."

The beef stearin used is a by-product of the margarine manufacture, and consists of the harder part of the beef fat from which the oleomargarine has been separated by pressure. Its price was recently about 36s. per cwt. The price of cotton-seed oil was about 23s. per cwt. The price of lard was about 47s. per cwt. It will thus be seen that there would be a large margin of profit if a compound consisting of 50 or 60 per cent. of the cheaper cotton-seed oil and beef stearin could be sold at the price of genuine lard; and this is probably the clue to the true explanation of the adulteration.

I do not enter into the question as to whether cotton-seed oil and beef stearin are better or worse than pure lard. I do say, however, that such a compound ought to be sold under its proper description, and not passed off on the public as pure lard. When a purchaser wants and asks for lard he should be able to get it, and not be supplied with another and a cheaper article. The selling of such adulterated lard is also a serious injury to fair and legitimate lard packers who will only supply pure lard, but who are undersold by the makers of the adulterated lard.

To detect cotton-seed oil and beef stearin in lard, and to form an estimate of the quantity, the following tests are chiefly relied on:—Some form of the nitrate of silver test for cotton-seed oil, the microscopical appearance of the crystals formed from an ethereal solution of the lard to detect beef stearin, the iodine absorption equivalent, and the specific

gravity. Useful information is also afforded by an examination of the colour, taste, smell, and consistency of the lard.

The Nitrate of Silver Test.—This is based on the reducing action of cotton-seed oil upon nitrate of silver, the reduced silver imparting a colour to the lard. I have been unable to obtain constant or trustworthy results with this test as applied by Beechi (see "Analyst" of September 1887), who, I believe, first proposed it, nor have I been more successful with the more complicated modification of Milliau (see "Analyst" of May 1888), which consists in applying the test to the fatty acids separated from the lard, nor with the several other modifications of this test which have been published. I obtain, however, very regular and certain results by adding an alcoholic solution of nitrate of silver to an ethereal solution of the lard. The method is as follows:—40 drops of the melted lard are placed in a test tube, and dissolved in 10 cc. of ether, and to the solution 2 cc. of an alcoholic solution of nitrate of silver (1 of nitrate of silver to 100 of alcohol) are added. The tube and its contents are left to stand for five or six hours in a place protected from light. If the lard contains cotton-seed oil the silver is reduced and imparts a maroon colour to the solution—the depth of the colour depending on the proportion of cotton-seed oil the sample contains. By comparing this colour with the colours produced in solutions of pure lard to which known percentages of cotton-seed oil have been added, a close approximation to the amount of cotton-seed oil in the sample can be obtained. Five per cent. of cotton-seed oil in a lard can be readily detected by this method.

Test for Beef Stearin.—The positive evidence of the presence of this substance in lard is best obtained by examining under a microscope the crystals formed from an ethereal solution of the lard, as proposed by Dr. Bellfield, of Chicago, and described in the "Analyst" of April last. For this purpose I use the ethereal solution of the lard mentioned in the last paragraph. Should crystals not form in the cooled solution the cork of the tube is removed and a loose plug of cotton wool is substituted. The solution is then left to evaporate spontaneously until crystals form. It is sometimes necessary to redissolve the crystals, if they have been formed rapidly, by warming the solution, and sometimes adding a little more ether, so as to obtain crystals which have been slowly formed. Some of the crystals are then removed by a pipette, placed under a microscopic slide, and examined. The crystals of beef stearin form curved tufts somewhat of the shape of the short tail of a horse. The terminals should be pointed and hair-like. Lard crystals are usually found in oblong plates, occasionally radiated, and have oblique terminals.

The Iodine Absorption Test.—This was first described by Hübl, whose method is given in the J. Soc. Chem. Ind. 1884, page 641. According to my experience with lards of known purity, I find the iodine absorption equivalent of pure lard when tested by Hübl's method to vary from 57 to 63 per cent., and cotton-seed oil to vary from 105 to 116 per cent. Were the lards to be examined for only mixtures of cotton-seed oil and lard, it would be easy to arrive at a fairly close approximation to the actual amounts of each present from this test alone. This, however, is never the case, as probably all lards which contain cotton-seed oil have also had beef stearin added to make the mixture of a suitable consistency. Beef stearin has an iodine absorption of from 23 to 28 per cent., whilst beef fat, which may

also have been used as an adulterant, has an iodine absorption of about 11 per cent. This, unfortunately, complicates the calculation of percentage amounts of impurity from the iodine absorption equivalents. Most of the adulterated samples, however, have hitherto contained cotton-seed oil in such large quantity, and the iodine equivalent is so high, that a very substantial adulteration can be certified to without taking into account the effect of the beef stearin. When, however, the amount of cotton-seed oil is ascertained by the nitrate of silver test, a near approach to the amount of beef stearin also present can be calculated from the iodine absorption, after making allowance for the influence of the known quantity of cotton-seed oil. If the lard is found to be a mixture of lard and beef stearin or beef fat without cotton-seed oil, the calculation of the proportions of each is simplified; but as at present there are no known means of distinguishing beef fat from beef stearin in lard, it is necessary to calculate from the lower iodine absorption of beef stearin, and thus the amount of beef stearin may be understated. If the iodine absorption of such a lard be found to be 42 per cent., it will be safe to conclude that the lard contains one-half beef stearin and one-half lard, calculating the pure lard iodine equivalent at 61 and that of the beef stearin at 23 per cent., as $61 + 23 = 84 \div 2 = 42$.

The Specific Gravity Test is also a useful corroboration of the other tests, for cotton-seed oil is higher in density than lard or stearin. It is customary to take the gravity at a temperature of 210° Fah. as compared with water at 60° Fah., and this is best done with a Westphal balance. At 210° Fah. pure lard has a gravity varying from 860 to 861, cotton-seed oil is 868, and beef stearin 857. Lard adulterated with cotton-seed oil is usually comparatively high in gravity. Some adulterated samples which have come under my notice have had a gravity of 863.5.

Mr. Jones, of Wolverhampton, has suggested in the "Analyst" for September last, a qualitative test for cotton-seed oil based on the stiffening effect which such oil imparts to a mixture of lard when sulphur chloride is added to it. This is a useful corroborative test.

Should the lard contain water, this is readily ascertained by the crackling effect produced when a portion of the lard is thrown on a red-hot fire, or into a red-hot platinum dish. Its amount is determined by drying at 212° Fah. a known weight of the lard in a flat-bottomed straight-sided dish until it ceases to lose weight.

It is satisfactory to be able to state that in this district, at any rate, the cotton-seed oil adulteration of lard is now seldom or never met with. This is owing to the prompt action which the authorities have taken in the matter, and also no doubt to the desire of wholesale dealers to avoid purchasing such lard now that they know of the existence of the adulteration. There are still many samples to be met with which contain very large admixtures of beef stearin or beef fat.

Notices of papers and communications for the meetings to be sent to the Local Secretary.

The Third Meeting of the Session was held in the Societies' Rooms, 207, Bath Street, Glasgow, on Monday, 7th January 1889.

MR. E. C. C. STANFORD IN THE CHAIR.

THE CHAIRMAN said that before commencing the ordinary business of the meeting it was necessary that he should refer to a very mournful occurrence that had taken place since last meeting. The hand of death had been very busy in the Section of the Society with which those present were connected. They had not got over the loss of their esteemed friend, Dr. Wallace, before they had to mourn the loss of one even more closely connected with the Society—their late Chairman.

He could not trust himself to say much about either of these two well-known men. They were very old comrades of his, and he could not look around the benches without being reminded of both of them very much. He would only say, however, that two more practical chemists, and two more amiable men, he had never been associated with, and that when he expressed his deep regret at their being taken away he was sure he was simply expressing the opinions of all who knew them.

ON EVAPORATION BY MULTIPLE EFFECT.

BY F. J. ROWAN, C.E.

THE value of steam as a heating medium, and the fact that the boiling point of liquids varies with the pressure, have been long known, and are the basis of the use of the ordinary vacuum pan. It is only within a comparatively recent period, however, that these principles have been taken advantage of in anything like a complete way in connexion with the evaporation of liquids.

De la Roche and Bérard estimated that the quantities of heat contained in equal weights of water and air at the same temperature are in the ratio of 374.6 to 100; or that the heat which is liberated when water cools down 100° is sufficient

to raise the temperature of 3.74 times as much air to the same extent. Regnault's later results correspond with the factor 4.21, giving even a larger heating value. Moreover, in passing into the state of vapour, water absorbs 5.36 times as much heat as is required to raise its temperature from 0° C. to 100° C. (32° to 212° F.), and this quantity of heat becomes latent, that is, it produces no increase of temperature in the steam, and therefore is not shown by the thermometer, but becomes again sensible when the vapour is condensed. Thus 1 lb. of steam at 212° F. (100° C.), in condensing to form boiling water, will yield sufficient heat to raise the temperature of 5.36 lbs. of water (or 4.21 × 5.36 = 22.6 lbs. of air) to 212° F.

Various devices have been introduced in order to make use of this convenient store of heat, and of those for dealing with liquids. The stills of Dorn, Derosne, and Coffey illustrate the class in which the steam is in contact with the liquor to be heated, whilst the ordinary vacuum pan for sugar making represents a different class, in which the steam is kept separate from the liquid being heated, and some of the energy required for evaporation is transferred to the work of producing a partial vacuum in the vessel containing the liquid.

The lowering of the boiling point of water by diminution of pressure is shown by the following table:—

The temperature of water boiling at atmospheric pressure is ° F.		
	under 5 ins. vacuum is	195
"	" " 10 "	185
"	" " 15 "	160
"	" " 20 "	150
"	" " 25 "	130
"	" " 26 "	120
"	" " 27 "	112
"	" " 28 "	100
"	" " 29 "	72
"	" " 29½ "	52

Other liquids follow a similar rule, but have different normal boiling points; and even water, when containing sugar or other substances in solution, has its temperature of boiling at atmospheric pressure raised. It is apparent from these facts that if in several vessels there are different degrees of vacuum produced, we can have a descending scale of boiling temperatures, so that vapour of comparatively low temperature can be utilised as it is produced. "The different boiling points of a liquid under different pressures can thus be utilised by making the vapour given off in boiling the contents of the first vessel at a certain pressure form the heating agent of the liquid boiling in the second vessel at a lower pressure, the vapour from this second vessel forming the heating agent in the third, and so on."

This principle was applied in what is known as the Rillieux system, and governs all forms of what are now called "Triple-effect" (or triple effect) apparatus. The Rillieux system utilised "the latent heat of the vapour of liquids boiling under a low vacuum to boil a second pan working under a higher vacuum. The usual limit to this system is four pans, thus utilising the latent heat four times and reducing the fuel to nearly one-fourth of that required for open evaporation or single vacuum pans. As generally arranged, all the boiling liquids in the system are under a partial vacuum; the first under about 5 inches, from which the vapour is taken to boil a second under 12 inches vacuum; from this to a third, boiling under 19 inches vacuum, and from this to a fourth, boiling under 27 inches vacuum.

"In liquids liable to injury by heat, the total variation of temperature available under ordinary

conditions is that between the temperature of steam at 5 lbs. pressure per square inch (227° F.) and the temperature of a solution at 30° Baume boiling under a vacuum of 26 inches (131° F.)—a total of 96° F. With a triple effect (or three vessels), however, there is steam at 5 lbs. pressure in the drum or shell of the first effect, and the liquid in the tubes—at atmospheric pressure—boils at 227° F., giving off vapour at 212° F. This vapour at 212° F. passes into the shell of the next effect and boils the liquid in the tubes of this effect under 14 inches vacuum, giving off vapour at 161° F. This again passes to the shell of the third effect and boils the liquid in the tubes under a vacuum of 26 inches, the boiling point of this liquid (supposing it to be a concentrated solution of 30° Baume) being 131° F.

"It is a point worth noting that where the liquid is a solution of solids in water, the vapour will always be at the temperature of boiling water at the pressure to which the liquid is subjected at the time, whilst the liquid itself will be slightly warmer."

The total difference of temperature in evaporating liquids liable to injury by heat being, as mentioned above, 96° F., whilst the amount of heat transmitted through the tubes (and therefore the work done) is practically proportional to the difference in temperature, it is evident that the same work is done whether the whole of this difference is in one vessel or is subdivided among several vessels. In other words, "a double, triple, or quadruple effect can only do the work of a single effect the size of the first vessel of the multiple effect; but it does it with a half, a third, or a fourth of the quantity of steam or fuel respectively."

Fig. 1 illustrates the arrangement of triple effect apparatus manufactured by Messrs. A. and W. Smith and Co., of Glasgow, who have been kind enough to furnish the illustration and information concerning

this apparatus. This apparatus is generally composed of three vessels, which may be placed either vertically, as shown in the illustration, or horizontally. Each of the vessels has a calandria, or tube-chamber, filled with small brass tubes, in the lower part of the vessel. The steam, which under ordinary working conditions is merely the exhaust steam from the engine connected with the apparatus, is admitted to the lower part of the chamber surrounding these tubes and acts upon the liquor inside the tubes, the level of the liquor being three-fourths of the height of the chamber. The steam or vapour rising from the surface of the liquor in this first pan enters into the tube-chamber of the second pan and boils the liquor in it. The steam or vapour from the surface of the liquor in the second pan enters the corresponding tube-chamber of the third pan, and boils the liquor which it contains. The vapour from this pan is drawn through the condenser by means of a vacuum pumping engine, which acts on the other pans also.

In its normal working it will be observed that the steam admitted into the first chamber is the actual heating medium for the three vessels. The apparatus is generally fitted with isolating valves, so that any of the pans can be thrown off at pleasure.

The temperature is highest in the first pan and lowest in the third; whereas the quality of the vacuum is arranged in the reverse order, it being highest in the last pan, which is nearest to the condenser and vacuum pump. This distribution of temperature and vacuum is said to be well suited to the evaporation of sugar liquor. The pans are fitted with eye-glasses, gauge-cocks, and other appliances necessary for the manipulation of the liquor from one pan to another, and for testing its consistency during evaporation. The whole apparatus is generally mounted on a cast-iron framework composed of columns and girders in order to render it accessible.

Fig. 1.

Although, in the form of apparatus just described, the liquor being evaporated is inside the small tubes, and the steam used for heating it is outside, in the triple-effect apparatus, as ordinarily arranged, the reverse order has usually been maintained.

The influence of the highly ingenious Yaryan apparatus has doubtless been felt in this and other details, but the action of the Yaryan evaporator is sufficiently distinct to demand separate description. The great objections found to exist against multiple-effect apparatus as usually constructed are the high

temperature to which the liquor is exposed in the first vessel, and the length of time which is required to treat the volume of liquid contained in it. In the manufacture of sugar with the ordinary triple effect the heat of the first effect, which reaches to nearly 200° F., combined with the long time to which the liquor is subjected to it, is a fruitful source of "inversion" of the sugar. With the Yaryan system, however, frequent tests with the polariscope demonstrate that there is no inversion, and consequently no loss of sugar from that cause.

The Yaryan Evaporator.—The ingenious invention of Mr. Homer T. Yaryan, of Toledo, Ohio, U.S.A., has met with a very large measure of success from its first introduction in America in 1886, and has in large measure superseded all previous attempts to produce economical evaporation by machinery. Mr. Yaryan adopts in his apparatus the two principles of "evaporation in a vacuum" and "evaporation by multiple effect." The evaporator itself consists of a series of straight tubes, passing from end to end of a shell or drum, and coupled together by an ingenious arrangement of "pockets" to form coils, the main advantage gained by this design being the great ease with which the straight tubes can be examined or cleaned. As a rule, the coils consist of an odd number of tubes, the inlet being at one end of the evaporator and the outlet at the other. At the outlet end of the evaporator is a separating chamber, in which the liquid discharged from the tubes is completely separated from the vapour. Below the separating chamber is a "collecting chamber" into which the liquid flows, whence it is drawn, by the superior vacuum, into the vaporising coils of the second effect, in which it undergoes a second process of evaporation by means of the vapour which comes, through the vapour pipe at the top of the separating chamber of the first effect, into the shell of the second effect.

This principle of "multiple effect" can be repeated in the Yaryan to an almost indefinite extent, its limit being gauged only by the commercial aspect of the question.

The evaporation in the Yaryan apparatus differs from that which occurs in previous systems in that it takes place in the interior of the above-mentioned vaporising coils, the heating agent being outside the tubes; and as the rate of the feed of liquid to be evaporated is arranged so that it cannot fill these coils, there is never any depth of liquid to be displaced by the vapour in its endeavour to escape from the heating surface. In addition to this, the rapid circulation induced by the formation of the vapour in the interior of the tubes promotes a movement which brings into play the whole of the heating surface in a manner which has never before been effected. Tests taken from Yaryan evaporators

in operation have shown an evaporation per square foot of heating surface of more than double that of any evaporator previously invented, whilst by the new principle embodied in Mr. Yaryan's invention, evaporation by multiple effect can be carried further in his apparatus than in any other.

As an evidence of the practical results obtained by the Yaryan evaporator, over one hundred machines, with a daily evaporating capacity of over 3,000,000 gallons, and concentrating a variety of liquids, have been started during the last two years, and all are giving great satisfaction.

The applications of the Yaryan evaporator are very extensive, as the following list will show, the liquids named having all been successfully dealt with:—Solutions of sugar, glucose, glue, glycerin, beer worts, grape must, waste alkali liquors from paper mills, bark extracts, dyewood extracts, tannin, liquid beef, pure caustic soda, tank waters from slaughter-houses, &c.

It has also been applied to the concentration of milk and to the production of distilled water from sea or impure water. In fact, it can be applied to almost any liquid requiring concentration.

The general arrangement of the apparatus is shown in Fig. 2. As will be seen, it consists of three or more horizontal vessels mounted on a light staging. It is provided with a condenser and pumping engine for maintaining a high vacuum in the last pan, and the engine is also provided with small pumps for feeding the liquor into the first pan, and withdrawing it, after concentration, from the last.

The action of the apparatus will be understood from the diagram, Fig. 3, giving a simplified section through one of the pans and "catch-alls." The heating tubes, surrounded by steam, are divided into units or sections, known as "coils," and consisting of five tubes, coupled at the ends so as to form one passage. One of these "coils" is shown in the illustration. Its action may be taken as typical of that of all the coils in the pan, of which there may be any number proportional to the work to be done. The liquor enters the first tube of the coil in a small but continuous stream, and immediately begins to boil violently. It is thus formed into a

Fig. 2.

Fig. 3.

mass of foam, which contains, as it rushes along the heated tubes, a constantly increasing proportion of steam. As the foam and steam cannot escape by the inlet end of the coil, and as steam is being continually formed, the mixture is propelled forward at a high velocity, and finally escapes from the last tube into an enlarged end chamber, known as the separator. This is provided with baffle-plates, against which the mixture of steam and liquor impinges on issuing from the tube. The liquor falls to the bottom, whilst the vapour passes on to heat the next pan.

The arrangement described is said to give an almost perfect separation of the liquor and vapour; but to make doubly sure, and to avoid the chance of losing any sugar, the vapour is next passed through the special form of catch-all shown in the illustration. This is also a part of Mr. Yaryan's invention. Here the vapour is divided by tubes into a number of small streams, each of which impinges against the end wall of the chamber, giving up any drops of liquid carried over. The vapour itself escapes by the central pipe. This catch-all is found in practice to prevent any detectable loss even when used for liquors far more liable to foaming than those dealt with in sugar manufacture.

The advantages claimed for the Yaryan apparatus are many and important. The duty of each square foot of heating surface is twice that which can be obtained in apparatus worked in the ordinary method. There is only a small quantity of liquor in the apparatus at any one time, and the circulation is rapid and compulsory. These are both very important points, seeing that the action of heat on sugar is injurious in proportion to the time during which it is applied, as well as to the intensity of the heat. The apparatus is found in use to be practically automatic and requires the minimum of attention. It can be started and stopped in far less time than is needed with the older apparatus, which will contain hundreds or even thousands of gallons of liquor.

The economy of fuel realised in the Yaryan arrangement of multiple-effect evaporation is thus stated by the patentees, to whom the author is indebted for the interesting particulars to which he has referred. A well-proportioned steam boiler, fired with good fuel, should evaporate $8\frac{1}{2}$ lbs. of water per lb. of coal. Each pound of steam condensed in the first effect will evaporate one pound of water, less the heat required to bring the liquid to be evaporated to its boiling point. If the initial temperature of the liquid were, say 50° F., and the

boiling temperature, say, 140° , there would be a loss of 90° . As there are about 966° of latent heat in steam, this loss would amount to nearly 10 per cent. Or, supposing the liquid is at the boiling point when it reaches the apparatus, every pound of steam condensed in the first effect evaporates 1 lb. of water, and in turn the vapour thus produced evaporates 1 lb. of water in the next effect, and so on. There is, of course, some loss by radiation of heat; but, as the vessels are small and easily lagged, this is reduced to a minimum: 16 lbs. of water will, therefore, be evaporated in a double-effect Yaryan apparatus, 23½ lbs. in a triple-effect, 30½ lbs. in a quadruple-effect, and 37 lbs. in a quintuple-effect for each pound of coal burned under the boiler.

With ordinary vacuum pan, or steam pan, boiling, only $8\frac{1}{2}$ lbs. of water will be evaporated per pound of coal used, while with direct firing not more than 5 lbs. of water per pound of coal can be evaporated.

DISCUSSION.

Mr. HAY said he would like to ask Mr. Rowan if he could give any idea of the comparative efficiencies of the different shapes of surface through which the heat was transmitted. In a still which he had at work the copper coil was zig-zag across the flat bottom of the still and the evaporation per superficial foot was $1\frac{1}{2}$ gallons per hour. But in a similar still in which the coil was hung round the sides—and not zig zag across the bottom—the evaporation amounted to $2\frac{1}{2}$ gallons. He should like to know whether there would be any advantage gained by using vertical tubes. He did not understand if the triple effect had a definite circulation. Mr. Rowan had said that the liquid within the tubes only reached three-quarters of the distance up the tubes, and that there was no liquid in the large upper space. Now, if the liquid did not reach the top of the tubes, how could it circulate in the apparatus? He had been unable to find out any means of calculating the efficiency of heating surfaces. Molesworth in his book of formula says that if a horizontal heating surface has an efficiency of 100, a vertical heating surface has only an efficiency of 50, while a horizontal surface with a downward aspect has no efficiency. Now he wished to know if this formula could be applied to tubes, as they are in the inside of the still.

Mr. R. A. ROBERTSON asked how the treatment of the juice in the ordinary triple-effect apparatus, diagrams of which was exhibited, could be described as similar to that in a Yaryan apparatus, and said

that the boiling of sugar liquors in ordinary multiple-effect apparatus, having the heating tubes partially filled with liquor was old and well known, and differed essentially from the system introduced by Mr. Yaryan, which consisted in feeding the liquor in limited quantities into a series of horizontal tubes, one end of each series of which was closed except to the extent of the inlet aperture, say $\frac{1}{4}$ in. to $\frac{1}{2}$ in. diameter. These partially-filled tubes being surrounded by steam, the vapour formed from the liquid within them, unable to escape in any other direction, rushed to the open end carrying with it the liquor in the form of foam or spray, and this mixture of liquid and vapour traversed the lengths of the apparatus as many times as found necessary to produce the required effect. In ordinary apparatus such as described by the author of the paper, although the partially-filled tubes threw up the liquor in something the same condition as existed in the tubes of the Yaryan, the evaporation at each discharge being very trifling the liquor had to circulate many times before any appreciable concentration was effected, whereas in Yaryan's apparatus the liquor flowed continuously through horizontal tubes of considerable diameter, and the desired degree of concentration was very rapidly effected without return to the inlet ends of the same heating tubes.

Another peculiarity of the Yaryan system was that, owing to the liquor going through the heating tubes in the form of spray, it was exposed to the heating surface in very thin films, and consequently such apparatus could be worked with lower temperature differences than so far appears to be possible with any other evaporating apparatus.

In a Yaryan apparatus working in London, the separate chambers of which were lit up by means of electricity, the violent spray discharge from each tube could be seen and fully verified the inventor's statements as to the condition in which, when his apparatus was properly worked, the liquor and vapour traversed the heating tubes.

The action of the Yaryan "catch-alls" or "safes," as sketched on the black-board by the author of the paper, had proved most efficient, as is shown by the fact that in the case of Yaryan apparatus employed for the concentration of spent alkali liquors in paper works, a few drops of which liquor would colour many gallons of water, the water of condensation coming from such apparatus is colourless and free from alkali.

Foaming liquors, such as those containing glucose, glue, glycerin, &c., which are most difficult to concentrate in ordinary apparatus, are from this very peculiarity amenable to successful treatment in the Yaryan apparatus, and by means of the separator chambers and "catch-alls," the resulting concentrated liquor and vapour can be separated without appreciable loss from boiling over.

Mr. ROWAN said, in reply to Mr. Haig, he had not had any practical experience of these forms of apparatus, but that having had occasion to collect information as to various methods of evaporation in the course of his work, he thought it would be interesting to the Society to have the subject brought before it. Therefore, as to the relative values of different forms of heating surface for evaporating liquids, he was unable to give the desired information from practical experience.

His experience of evaporating had been gained in connexion with steam boilers, and while he knew it was a fact that the relative value of heating surfaces were reckoned according to the method which had just been mentioned, it must not be forgotten that those values were merely stated in relation to the

travelling of the hot gases in one direction, viz., always tending upwards. Some years ago he had controverted that statement, which had been made by several engineers, because it was apparent to any one that if the direction of the movement of the hot gases was reversed, all the estimates of heating surface would be erroneous. Take the case of passing the hot gases downwards over the heating surface of boilers before these hot gases were allowed to escape. It was well known that in so doing you reduce the rate of travel of these hot gases and allow the colder portions to escape first, and that system might be carried out to any extent, giving complete control over the rate of escape of the gases, and consequently the relative values of the different forms of heating surfaces were entirely altered.

Where the gases were travelling horizontally, and then vertically, it stood to reason that horizontal surface was more valuable than vertical surface, because the gases were delayed in passing over the horizontal surface, whilst their period of contact with vertical surfaces was short. But if the rate of the movement of the hot gases was controlled on the vertical surface, it was just as valuable, and in fact, in his humble opinion, even more valuable, because it was more easily dealt with as regarded the necessary circulation of the liquid.

As regards Mr. Robertson's remarks, he did not say that the triple effect worked on the Yaryan principle, but that the Yaryan invention had evidently influenced the design to the extent of having the liquor contained in the small tubes, instead of its being in a mass with the heating tubes passing through it.

ON A PECULIAR CRYSTALLINE ALLOY OF COPPER, TIN, AND LEAD.

BY A. FRENCH.

OLD furnace bottoms are good hunting grounds for those who have the time, and are imbued with a spirit for inquiry. Unfortunately it too often happens that those who have the opportunity of finding new things or of observing strange phenomena not infrequently lack the time and facilities, and, it may be, the talent and ability to investigate the discovery as fully as it requires, and those who are more favoured with time, apparatus, and learning are mostly always located within the walls of a city laboratory and may never hear of the rare opportunities which they are missing by not being on the spot.

The crystalline alloy which I show on the table was found within a cavity in the bottom of a cupola furnace which was being cut out, after running on material containing oxides of lead, copper, tin, iron, and a little antimony. The cavity evidently had been filled, whilst the furnace-bottom was working, with the ordinary impure lead which was being smelted, and which contained somewhere about 3 per cent. tin, 1 per cent. antimony, and 1 per cent. copper, leaving about 95 per cent. of lead. And when the furnace was cooling down very probably the molecular forces which determine crystallisation would come into play, selecting out the necessary elements in the required proportions to form the greatest quantity of crystalline matter, according to a law analogous to that which determines the formation of crystalline minerals.

A few days after a furnace is put off lead begins to ooze out by cracks which take place in the slag of which the bottom is made, and cavities which are emptied of their liquid contents in this way frequently contain crystalline matter. The same thing may be seen in bull-dog slag from the puddling furnace, the cavities containing beautiful crystals of definite silicates of iron.

The interesting feature of the crystals which I exhibit to you is their resistance to oxidation. They have been exposed to the atmosphere, dry and wet, for several months, and are as bright to-day as at first; strong sulphuric acid, even when boiled, has scarcely any effect in corroding them, in fact it is only after boiling for some time in the acid that the lustre of the crystals is affected. Hydrochloric acid has very little effect on them either cold or hot, and whilst hot nitric acid attacks them, still there are other and smaller crystals amongst them which resist the action of boiling nitric acid for a long time, but they dissolve at once in aqua regia.

The leady crust which forms the matrix or base of the crystals is easily attacked by hydrochloric or nitric acid.

The crystals are in the form of plates and flat lengthy four-sided prisms, the narrow sides bevelled at the angles of about 42° and 138°. They appear to belong to the oblique prismatic system, having the three axes all unequal, and the two shorter or cross ones at oblique angles of about 42° and 138° to each other, but both of these are at right angles to the principal or long axis.

I have already said that there are small crystals present which are attacked with difficulty by nitric acid; these show a much larger proportion of copper and less lead than the average of the specimen, but their quantity is so small that an accurate determination cannot well be made without destroying the whole. The analysis of the whole specimen is not by any means constant, and I can only offer this as the best of three trials on $\frac{1}{2}$, 1, and 2 grms

Lead	65.89

DISCUSSION.

Dr. MILNE asked if Mr. French had made any trials as to the relative hardness of this alloy as compared with corresponding alloys.

Mr. FRENCH said that from the slight trial he had made, the alloy showed a fair degree of hardness, but he thought it would be best characterised if he called it brittle.

In reply to an inquiry as to what purposes it might be used for, he said that if he could discover a way to make it in quantity, he thought it could be used for several useful purposes, but that was a matter which would require to be investigated.

Journal and Patent* Literature.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

Steam Boiler Explosions in the German Empire during the Year 1887. Chem. Zeit. 12, 1444—1447.

FOURTEEN explosions took place during the year 1887. The official investigation showed the following results:—(1.) *Explosion of a cylindrical boiler with heater at the paper-mills of Nücklich and Co., Eisenberg.* Cause of the

Fig. 1.

Figs. 2 & 7.

Fig. 3.

Fig. 4.

Figs. 5, 6, & 13.

Figs. 8 & 9.

Fig. 10.

Fig. 12.

explosion was the corrosion of the plates in the bottom boiler. (2.) *Explosion of a vertical boiler with cross tubes, at the flour-mills of H. Bucher, Kaldenkirchen.* The plates were of inferior quality, and of cold-short iron. The explosion was due to an excessive pressure of steam. (3.) *Explosion of a cylindrical vertical boiler in the iron-works*

* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.	$\frac{1}{2}$ d.
Above 8d., and not exceeding 1s. 6d.	1d.
" 1s. 6d. " " 2s. 4d.	$\frac{1}{2}$ d.
" 2s. 4d. " " 3s. 4d.	2d.

of P. Weber, Dortmund. Cause of the explosion was want of water in the boiler. (4.) *Explosion of a vertical cylindrical boiler with flue-tubes.* The bottom of the boiler had been protected by a cast-iron ring, but on one occasion, before getting up steam, a portion of the ring broke off, which caused an unequal distribution of heat. A fine fissure was thereby formed, through which the boiler emptied itself, thus causing it to run short of water. (5.) *Explosion of a horizontal boiler with heater at the saw-mills of Kolk and Schregel, Haltern.* Cause of the explosion was excessive steam pressure, but how this arose could not be discovered. (6.) *Explosion of a horizontal boiler with heating-tubes, at the brown coal mine, Köttschau.* A patch was put upon the plates of the bottom boiler six or seven years before the explosion. The patch gradually rusted away without being noticed, and the local weakness of the plate at last caused the explosion. (7.) *Explosion of a marine boiler on the steamer "Margarethe."* Want of water caused some tubes to get red-hot, one of which burst. (8.) *Explosion of an elephant boiler at the colour-works of F. Bayer and Co., Elberfeld.* Too hard firing and frequent overheating caused local weakness of the plates, which at last gave way. (9.) *Explosion in the iron-works at Friedenschulte.* Here 22 boilers were placed in one row, all of which were destroyed by the explosion. The quality of the plates was presumably not very good. The boilers were heated by gases from the blast-furnaces, and opinions are divided on the question whether an explosion of these gases may not have caused a concussion in the first instance, which gave rise to the explosion of the boilers. (10.) *Explosion of a Cornish boiler at the whiskey distillery of A. Winkler, Kleinmilkau.* The flue-tube collapsed and was torn. The points of rupture showed a thick layer of oxide, which pointed to a fracture of long standing, and excessive pressure of steam at last had overcome the resistance of the weakened plates. (11.) *Explosion at a paper-works.* A plate in the shell of the bottom boiler became red-hot, and ruptured. Ten tubes were bent by the explosion. (12.) *Explosion of a boiler on the steamer "Wilhelm."* Owing to want of water, the roof of the fire-box was heated too strongly, and gave way. (13.) *Explosion of a horizontal boiler at the Lugau Colliery, Zwickau.* A plate of the bottom boiler was weakened by corrosion from the outside. At the point of fracture, the plate was only from 1 to 2 mm. thick.—S. H.

PATENTS.

An Improved Evaporating and Condensing Apparatus for Producing Fresh Water from Sea Water for Drinking Purposes and for Boiler Feed. W. F. Pamphlett, Portsea. Eng. Pat. 15,586, November 14, 1887. 8d.

This invention purposes taking advantage of the application of a vacuum to a liquid that is to be evaporated, for reducing the temperature of evaporation, with a view to the economisation of heat. For the same purpose the pre-heated sea-water used for condensing, as it issues from the hot well of a condensing marine engine, is utilised as the liquid of evaporation. It is circulated through steam-heated, tubular, closed chambers, in which a vacuum is kept up. The vapour given off may be condensed for drinking purposes or for boiler feeding in a tubular condenser of similar construction. The drawings indicate several ways of arranging the apparatus.—B.

Improvements in Apparatus for Distilling Water, applicable also for Heating Purposes and for Feeding Boilers. C. Howe and J. H. Beckwith, Colechester. Eng. Pat. 9548, June 30, 1888. 8d.

STEAM is taken from a steam boiler into a coil placed in a secondary boiler situated above the main boiler, and filled with the salt or impure water submitted to distillation. The water which condenses in the heating coil flows back into the main boiler, and the vapour produced in the secondary boiler is led into a condensing worm in a second vessel, where it is condensed, imparting its heat to the liquid subsequently passed into the secondary boiler. The arrangements for heating purposes are similar.—C. C. H.

Improvements in Evaporating Apparatus. S. M. Lillie, Philadelphia, U.S.A. Eng. Pat. 12,391, August 28, 1888. 8d.

FIG. 2 shows the construction of one of the evaporators E in Fig. 1, which illustrates the combination of three such evaporators and the requisite connections forming a multiple-effect apparatus. Through the pipe v^1 the liquid to be concentrated is introduced, and after distribution by D^1 , passes through the perforated cover-plate p^2 into the feed-chamber G, overflowing into the tubes b in the form of a

Fig. 1.

Fig. 2.

film coating the insides of the tubes. The whole tubes are heated by means of steam admitted through *S* into the heating chamber. The concentrated liquor falls into the collector *P* and through the float-trap *F* into the pump *C*, by which it may be returned into the evaporator in the case of a single effect, or, as shown in Fig. 1, into the next evaporator in case of a multiple effect. The vapour passes through the annular spaces *t*, round the exterior of *P*, and thence into the vapour main *B*. As shown in Fig. 1, the vapour from one effect heats the tube-chamber of the next, and finally passes, in the case of the last of the series, into the condenser on the vacuum pump *M*. The flow of liquid through the whole series is regulated by means of the floats *F*. The invention and its details are covered by 28 claims.—C. C. H.

II.—FUEL, GAS, AND LIGHT.

Note on the Petroleum and Native Paraffin of New Zealand. R. W. Emerson MacIvor. "The Gas World," 18, December 1, 1888.

PETROLEUM has been known to exist in several localities in New Zealand since 1866, but it is only within recent years that attempts have been made to ascertain whether the oil occurs in sufficient quantity to have a commercial value. The first discovery was made at Waipatu, Poverty Bay, on the east coast of the provincial district of Auckland, and the second one at Manutahi, Waipatu, East Cape. Many thousands of pounds have been spent in boring operations, and, though fair quantities of good oil are generally obtain-

able, no steady supply has been come upon. The depth of the borings made has exceeded 1,000 feet. The oil obtained from the first locality named much resembles Canadian oil. By several successive distillations, and treatment with acid and alkali, the crude material yields from 65 to 70 per cent. of excellent illuminating oil, having a specific gravity of 0.844 at 15.5° C. The oil obtained at Manutahi has a pale brown colour, is nearly quite transparent, and has a specific gravity of 0.830 at 15.5° C. It contains very little solid paraffin, and on distillation yields about 80 per cent. of illuminating oil, fit for use in ordinary lamps. When subjected to two more distillations, about 65 per cent. of oil of specific gravity 0.812 is obtained.

The natural gas which escapes from the ground in some places consists chiefly of methane, but burns with a bright luminous flame, owing to the presence of higher paraffins in the form of vapour.

Large quantities of a white or grey, somewhat gelatinous, substance occur on the property of the South Pacific Petroleum Company, and examination has shown it to vary in composition. Samples submitted to W. E. Dixon, of Sydney, N.S.W., J. Cosmo Newbury, of Melbourne, and the author, were found to contain a large percentage of solid paraffin, extractable by the ordinary solvents. Later samples, however, were found to be free from paraffin, and to consist of a substance which, when heated, would neither melt nor burn, but simply charred. Skey, the chemist to the New Zealand Geological Survey, examined the material and reported it to be a sort of *dopplerite*, or, at least, a body allied in chemical composition to that mineral. The author found, however, that on charring it "the smell of burning feathers" was perceptible, indicating the presence of nitrogen.—W. S.

Improvements in Apparatus for the Combustion of Liquid Hydrocarbons. W. M. Chinnery and P. Tarbutt. London. Eng. Pat. 624, January 14, 1888. 8d.

THE apparatus here described is an improvement upon that specified in Eng. Pat. 13,752 of 1886 (this Journal, 1887, 651). The combustion chamber is divided into two compartments by a horizontal partition, the lower communicating with the upper by a central adjustable nozzle. The upper compartment contains liquid hydrocarbon kept at a fixed level (below the delivery point of the central nozzle) by communication with a reservoir, which is supplied automatically by means of a suitable valve. This upper compartment is provided with a conical cover, open at the top, and perforated with a number of small holes near its lower edge. This is surmounted by an outer cover of the same shape, so that an annular space exists between the two. To commence operations a light is applied to the oil in the upper compartment, which undergoes incomplete combustion with the air entering through the perforations in the cover. Compressed air is now forced into the lower compartment, and issues jet-wise through the nozzle-mouth in the upper compartment. It draws away the hydrocarbon vapours here disengaged by the heat of the incomplete combustion, and escapes from the top of the conical cover as an intensely luminous flame. This is fed with air by the heated current continually passing upwards through the annulus between the two covers.—A. R. D.

Improvements in Furnaces for Aiding Combustion. J. Beveridge, Barrow-in-Furness. Eng. Pat. 1871, February 8, 1888. 8d.

HOLLOW grate-bars are employed, open at the front end, and communicating at the back with a chamber of fire-

resisting material inside the fire-box. Air is caused by a natural or forced draught to pass through the hollow fire-bars into the said chamber, whence it escapes by suitable openings to mingle with the fire gases in the flue, and, being in a highly heated condition, promotes a very perfect combustion. The flue is preferably packed with checkered work or regenerative passages.—A. R. D.

Improvements in the Construction of Coke Ovens. A. F. Link, London. From P. T. Bauer, Munich, Bavaria. Eng. Pat. 11,040, August 7, 1884. Amended September 22, 1888. 11d.

THE amendments refer mainly to the flue arrangements for dealing with the hot air supply and products of combustion. The specifications with its drawings should be consulted. (See also this Journal 1885, 486.)—A. R. D.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

On the so-called "Free Carbon" in Coal Tar. H. Köhler. Dingl. Polyt. J. 270, 233–240.

WHEN coal tar is extracted with a suitable solvent until no more is dissolved, a brown-black powder of velvety appearance is left, which is the so-called "free carbon" of coal tar. The author discusses the various views which have been advanced as to the origin and formation of this substance, and agrees with Kunath that it is chiefly produced by the decomposition of heavy hydrocarbons on the red-hot walls of the retorts, only a very small percentage being attributable to coal dust mechanically carried over. Two analyses gave the following figures:—

	I.	II.
	Per Cent.	Per Cent.
Carbon	90.836	91.120
Hydrogen	3.058	3.129
Ash.....	0.398	0.872

and many determinations of the ash of the "free carbon" in different tars gave, as mean, 0.412 per cent. of ash.

The relations between the percentage of "free carbon" and the properties of the tar are next considered, and from a comparison of figures showing the specific gravity and percentage of "free carbon" it is seen that there is a distinct relation between them, the specific gravity increasing with high, and falling with low percentage of "free carbon."

It seems probable that the consistency of tar is decidedly affected by the proportion of "free carbon," one sample, containing 23 per cent. of "free carbon" being very pasty, while another, with only a per cent., had the consistency of thick oil. It was also found in general that tars containing much "free carbon" were richer in heavy oils and naphthalene, and those with little, richer in benzene and light oils.

In regard to the influence of the "free carbon" on the working of coal tar, the author treats of the troublesome property many tars have of frothing during distillation, and ascribes this almost entirely to the "free carbon" contained, and not as has hitherto been supposed, to water. To prove this view he tried two mixtures of a normal tar, the one with 10 per cent. of water added, and the other with 10 per cent. of lampblack, and found that the sample with the added water distilled without frothing, whereas that with the "free carbon" could not be kept in the retort, the greatest care being used in both cases.

In conclusion, he says that to a certain degree the percentage of "free carbon" indicates the worth of a gas tar, a small percentage meaning a larger quantity of benzene and light hydrocarbons, in general, but this is only true up to a certain limit, which is below the "free carbon" percentage for normal tars.

From this point it is often noticed that tars containing the same amount of "free carbon" sometimes produce more anthracene and heavy hydrocarbons, or more benzene and light hydrocarbons, probably depending on the mode of distillation or the nature of the coal used. But when the percentage of "free carbon" considerably exceeds the normal, a bad yield of valuable products may be counted on, and the quantity of pitch will be large.

The author has had ample opportunity of proving that the quantity of pitch can be approximately calculated from the percentage of "free carbon" in the tar, if the percentage of "free carbon" in the pitch of the required degree of hardness be known.

If K be the percentage of "free carbon" in the pitch, and k the percentage of "free carbon" in the tar, then $K : 100 = k : x$.

Good medium hard pitch from most German tar distilleries contains on the average about 28 per cent. of "free carbon," and as the result of many estimations the normal percentage of "free carbon" in tar is 16, so the yield of pitch from a normal tar is found thus:—

$$x = \frac{100 \times 16}{28} = 57 \text{ per cent.}$$

Of course, for each tar distillery the percentage of "free carbon" must be determined before the yield of pitch from the tar can be reckoned. As distillation experiments are only of value when carried out with large quantities (1 to 2 cwt.), and cannot always be easily made, the author points out that the estimation of the "free carbon" in a tar offers the most reliable and easy method of approximately judging of its value.—C. N. H.

IV.—COLOURING MATTERS AND DYES.

The Manufacture of Benzyl-Violet. O. Mühlhäuser. Dingl. Polyt. J. 270, 179–181.

THE commercial product consists chiefly of the hydrochloride of pentamethylbenzyl-pararosaniline. It is generally prepared by the action of 1 mol. of benzyl chloride on 1 mol. of pentamethyl-pararosaniline (methyl-violet). Another method, discovered by Caro and Kern, viz., the action of methylbenzylamine on tetramethyl-diamidobenzenophenone, has not hitherto been used for manufacturing purposes.

Laub is the first who prepared benzyl-violet. It was first produced, on an industrial scale, by Poirrier and Chappat, and their method, as described by Wurtz, is the one which, with certain modifications, is still in use. The manufacture comprises three distinct phases:—

1. *Benzylating.* This is performed in an enamelled cast-iron pan, provided with manhole and the usual metal pipe for the protection of the thermometer. The pan is placed in a water-bath, and can be connected with a condenser either for distilling or for reflux action. The pan is charged with 50 lb. of alcohol (96 per cent.). To this, while agitating, is gradually added 60 lb. of powdered methyl-violet, and the mixture boiled, the downward condenser having previously been shut off by means of a stop-cock. After about half an hour the violet is dissolved, and the pan having been cooled by means of cold water, until the temperature is 60°, 18 lb. of benzylchloride are added, and, after half an hour's stirring, 48 lb. of caustic soda solution of 31° B. The mixture is now heated under the reflux condenser for four hours at 80°. The mass is then treated with 10 gallons of warm water, and the alcohol, as well as other volatile products, distilled off with steam.

2. *Separation of the Crude Violet.* After cooling somewhat, the melt is emptied into a vat filled with warm water, boiled by blowing in steam and neutralised, while boiling, with 6 lb. of hydrochloric acid (sp. gr. 1.18). The solution is passed through a woollen filter after a short time, the residue in the vat boiled with water, filtered, and the combined filtrates, contained in an iron cistern, are treated with brine. After 12 hours, when all the violet has separated, the mother-liquor is removed by decantation.

3. *Purification.* The crude violet is now redissolved in boiling water, and boiled until all soluble colour has been separated from the insoluble portion. After 12 hours the clear liquor may be filtered through a double woollen filter, and further treated in the manner described by the author in the case of the manufacture of methyl-violet (this Journal, 1887, 434). The colour is finally dried in a copper jacketed pan at 55° and ground. The average yield is about 55 lb.

—A. R.

PATENTS.

Improvements in obtaining Colouring Matters for Dyeing and Printing. J. P. Griess, Burton-on-Trent. Eng. Pat. 4726, November 20, 1878. (Second edition.) 6d.

THESE are azo-dyes obtained by the action of the diazo-compounds of phenolic ethers, their sulphonic acids or chlorine-, bromine-, iodine-, hydroxyl- or nitro-substitution products, on the phenols or their sulphonic acids. A dye-stuff capable of replacing cochineal or lac dye, and giving yellow shade scarlets or reds is produced as follows: Anisidine, or an equivalent quantity of any of the higher ethers of amidophenol, is dissolved in concentrated hydrochloric acid of sp. gr. 1.17 and water, and diazotised with a 10 per cent. solution of sodium nitrite. The mixture is then added to a solution of the sodium salt of β -naphtholmonosulphonic acid, caustic soda or ammonia being added from time to time in order that the solution remains slightly alkaline. Part of the dyestuff separates as a dark red precipitate, the precipitation being completed by the addition of salt. Red colouring matters of a bluer shade are obtained by substituting for the naphtholmonosulphonate either β -naphthol disulphonic acid or a mixture of the sulphonic acids of β -naphthol formed in the following manner:— β -naphthol is dissolved in fuming sulphuric acid containing 85 per cent. of sulphuric anhydride, and the mixture heated to 110° C. for five hours. After removing the free sulphuric acid with lime and converting the sulphonic acids into the sodium salts, the latter are dissolved in water and treated with the same quantity of anisidine in the manner described above. The amido-sulphonic acids of the phenolic ethers may be prepared in two ways: 1. Anisidine (or any of its homologues) is mixed with four times its weight of sulphuric acid of sp. gr. 1.84, and the mixture heated to 100° C. for 3—4 hours until soluble in water. It is then treated with lime, the calcium salts decomposed with sodium carbonate, and the solution of the sodium salts evaporated to dryness. 2. Anisidine is dissolved in two parts of sulphuric acid of sp. gr. 1.84 and heated to 100° until soluble in water. The sulphonic acid is then converted as above into the sodium salt, and one part, by weight, of this is mixed with two parts of nitric acid of sp. gr. 1.48, the temperature being kept below 40° C. The nitro-sulphonic acid separates out and can be purified by crystallisation from water. It is converted into the amido-sulphonic acid by the usual reducing agents. Red colouring matters are obtained from these amido-sulphonic acids of the phenolic ethers, prepared according to either of the above processes, in the following manner:—The sulphonic acids of anisidine are mixed with hydrochloric acid of sp. gr. 1.17 and water, diazotised with a 10 per cent. solution of sodium nitrite, and this mixture added to a solution of β -naphthol, water and caustic soda, care being taken to maintain the mixture slightly alkaline. A dark red precipitate then separates out. Bluer shades are obtained by using the sulphonic acids of β -naphthol prepared in the manner described above. Purple dyestuffs are formed when the methyl or ethyl ethers of β -naphthol are

used in place of the phenolic ethers. The colours derived from α -naphthol are inferior to those obtained from the β -derivative.—T. A. L.

Improvements in the Manufacture of Colouring Matters. I. Leviustein, Manchester. Eng. Pat. 5692, November 30, 1882. (Second edition.) 6d.

THESE are yellow colouring matters obtained by the action of nitric acid on the mono- and disulphonic acids of nitroso- α -naphthol. The following is the method employed: 10 parts by weight of α -naphthol are dissolved in 40 parts of sulphuric acid of 170° Tw. at 100° C. The temperature is then increased to 130° for one hour, when the greater part of the α -naphthol is converted into a disulphonic acid. The mixture is then diluted with 30 parts of water and treated with 4.6 parts of sodium nitrite or a sufficient quantity to convert the substance into a nitroso- α -sulphonic acid, care being taken to keep the temperature below 10° C. 24 parts of nitric acid, sp. gr. 1.456, are then diluted with an equal weight of water and added to the above mixture. The whole is then allowed to stand for 2—3 days, when crystals separate out. An alternative method, which does not give such good results, consists in raising the temperature of the mixture to the boil when a separation of crystals takes place. The crystals have acid properties, dye a bright yellow, and may be used as such or converted into salts.

—T. A. L.

Improvements in and relating to the Manufacture of Blue and Bluish Azo-Dyes. B. Willeox, London. From F. Bayer and Co., Elberfeld, Germany. Eng. Pat. 1346, January 28, 1888. 6d.

ONE molecule of the tetrazo-compounds of benzidine, tolidine, or diamidodiphenol methyl or ethyl ether is combined with two molecules of β -naphthol- δ -sulphonic acid or of Schöllkopf's α -naphthol disulphonic acid L; or one molecule of the tetrazo-compound is combined first of all with one molecule of β -naphthol- δ -sulphonic acid or one molecule of Schöllkopf's α -naphthol disulphonic acid L and the intermediate product so formed combined with α - or β -naphthol, their monosulphonic acids, or with β -naphthol disulphonic acid R. The following are examples of the blue dyestuffs thus formed:—31.7 parts (by weight) of the hydrochloride of diamidodiphenol methyl-ether are dissolved in 1,000 parts of water, mixed with 36 parts of hydrochloric acid 21° B. and converted into the tetrazo-compound by the addition of a solution of 14 parts of sodium nitrite in 100 parts of water. This is then added to a soda solution containing 75 parts of the sodium salt of Schöllkopf's α -naphthol disulphonic acid L dissolved in 1,000 parts of water, care being taken that the solution always remains alkaline. The dyestuff is filtered off and dried. It dyes wool from a neutral, or cotton from an alkaline bath, greenish blue. If the 75 parts of the sodium salt in the above example be replaced by half that quantity, an intermediate product is obtained which is capable of being combined with an alkaline solution of α -naphthol or its sulphonic acids, to form blue dyestuffs of a reddish to a greenish shade. If equivalent quantities of benzidine or tolidine be substituted for the diamidodiphenol ether, the dyestuffs obtained are much redder.—T. A. L.

Improvements relating to the Production of Colouring Matters. H. H. Lake, London. From Leonhardt and Co., Mülheim, Germany. Eng. Pat. 2664, February 22, 1888. 6d.

THE action of heat on certain oxidisable inorganic or organic substances when mixed with free caustic alkali and paranitrotoluene sulphonic acid, or its salts "in a dissolving or distributing medium," gives rise to the formation of a number of colouring matters from yellow and orange to brown, which dye cotton without a mordant and are fast

to alkalis. The following oxidisable substances are mentioned: methyl and ethyl alcohols, glycerol, resorcinol, potassium xanthogenate, quinol, orcinol, naphthol, dioxynaphthalene and its sulphonic acid, pyrogallie acid, resorcylic acid, oxynaphthoic acid, gallie and tannic acids, and substances containing the latter, *e.g.*, sumach and catechu, oxyquinoline carboxylic acid, sulphurous acid, arsenious acid, and antimonious acid or its salts. The following serve as examples of the methods employed:—(1.) 10 kilos. of the sodium salt of *p*-nitrotoluene sulphonic acid are mixed with 30 litres of spirit or methyl alcohol, and heated in a vessel provided with an agitator and an inverted condenser. About 8 kilos. of caustic soda (40° B.) are then added gradually and the whole heated to boiling. The colouring matter is filtered off, pressed, and dried. (2.) 10 kilos. of *p*-nitrotoluene sulphonic acid are heated together with 20 kilos. of glycerol, and to this mixture are added 8 kilos. of caustic soda (40° B.) at about 50° C. The reaction is moderated by cooling, and the thick paste formed is stirred into 100 litres of boiling brine, and rendered acid preferably by acetic acid. The colouring matter is then filter-pressed and dried. (3.) 20 kilos. of the sodium salt of *p*-nitrotoluene sulphonic acid and 4 kilos. of resorcinol are dissolved in 50 litres of hot water; 20 kilos. of caustic soda (40° B.) are added, and the whole boiled up until no more colouring matter is formed. The latter is then precipitated by neutralising with an acid and by the addition of salt. (4.) 6.5 kilos. of arsenious acid are dissolved in 150 litres of water. 20 kilos. of caustic soda, and 20 kilos. of the sodium salt of *p*-nitrotoluene sulphonic acid are then added, and the mixture heated as long as colouring matter continues to be formed.—T. A. L.

ERRATUM.

This Journal, December 1888, 839: The second formula should be joined together, thus:—

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

Progress in the Chemical Technology of Textile Fabrics.
O. N. Witt. *Diagl. Polyt. J.* 270, 316—322.

CERTAIN new colours, such as Paraphenylene blue, Rhodamine, Nile blue, are described, of which an account has already been given (this Journal, 1888, 561).

Dinitrosoresorcinol is used much in cotton dyeing and printing for the production of deep bottle-green shades. Tin salt discharges the colour effectually. Those colours which have a direct affinity for vegetable fibre, the so-called substantive azo-dyes, are of great importance, since it has been discovered that they will also dye wool in neutral baths, sometimes after addition of salt or by rendering slightly alkaline with sodium phosphate or borax. The shades thus obtained stand milling very well and hardly "bleed" at all. Cotton may be dyed in the same manner, and consequently these colours are of great value in the dyeing of mixed fabrics. Printing with substantive azo-dyes requires much care. Addition of caustic soda is advisable. The following is a mixture for printing with Chrysamine-yellow:—

Water	10 litres.
Flour	2½ kilos.
Gum tragacanth	5 litres.
Marseilles soap	0.6 kilos.
Chrysamine	0.6 kilos.

Less trouble is involved and very excellent results are obtained by discharging these dyes with tin salt, or, better, a mixture of the latter with sodium acetate. When different colours are required in the pattern, the substantive azo-dye is mixed with such colours as Persian berries for yellow, with Methylene-blue and a little tannic acid for light blue, and for dark blue Alizarin S and acetate of chrome or Indophenol white in preference.

A new class of dyes of a similar kind is that of Primuline, and the colours derived from it, the so-called ingrain colours. A description of these has already been given by their inventor, A. G. Green (this Journal, 1888, 179). On dry distillation Primuline yields the yellow product known as Dahl's thiotoluidine. The ingrain shades are not very brilliant, but they stand milling remarkably well. Their production, however, requires much care on the part of the dyer.

Alizarin-black is a valuable dye, which was first described by Roussin under the name of Naphthazarin, and "The Badische Aniline and Soda Fabrik" have converted it into a marketable article by combining it with sodium bisulphite after the manner of Alizarin-blue. Wool is first cleaned with ammonia and a little soda, then 100 parts of it are boiled with 3,000 parts of water, 3 parts of potassium chromate, and 2½ parts of cream of tartar, for 2 hours. After standing over night the wool is dyed with Alizarin-black S.W.: 20 parts of this paste give a deep and very fast black. By taking less, good fast greys are obtained, which are shaded with Alizarin-brown or blue. Alizarin-black has lately also been used for printing. The method is the same as with Alizarin-blue.

The employment of alizarin-dyes for wool is on the increase; they are both brilliant and fast, and have also been tried for printing on woollen goods. The dyes are mixed with the acetates of aluminium or chromium for the latter purpose. The following shades may be thus produced:—

Dye.	Chrome Mordant.	Alumina Mordant.
Alizarin W.R. (paste)	Yellowish-claret ...	Yellowish-red.
" W.B. "	Bluish " ...	Bluish-red.
" S. (powder)	" " ...	" "
Alizarin-orange	Brownish-orange...	Orange.
Alizarin-blue S.W. ...	Greenish-blue.....	Reddish-blue.

Oxalic acid is often added to the pastes, as it fulfils its purpose better than acetic acid, *i.e.*, fixing of the colours. A number of recipes are given for making the printing pastes.

The "Farbenfabriken vormals F. Bayer and Co." has patented a method for the direct production of azo-colours by printing on the fibre. The diazo-compound is printed on the fibre with thickening, and then drawn through an alkaline solution of a phenol.

Reverting to the much-discussed question of the fastness or fugitiveness of the various artificial dyes, the author says that much depends on the manner in which the dyes are fixed; generally speaking, the anthracene dyes are very fast, whereas most of the triphenylmethane derivatives are the reverse. The indulines are remarkably fast; the enrhodines and safranines may be regarded as only fairly fast. No general rule can be expressed for the azo-dyes. Whilst some are very sensitive to light, others are extraordinarily fast. Thus Bordeaux S. of the "Berliner Actien-gesellschaft" (the Na salt of the sulphonic acid of

α -naphthylamine-azo- β -naphtholdisulphonic acid) is one of the fastest dyes we possess. Even the most delicate pink dyed on wool with this colour may be exposed to light for a considerable time without fading.—A. R.

Note on some "Conversion Colours." Bull. Soc. Ind. Rouen, 1888, 285—287.

On the 12th April 1877, the late F. Lamy deposited with the Society a sealed note concerning the "conversion colours" obtainable with Gallein and Coerulein in calico printing. In this note M. Lamy records that when a colour composed of Anthraviolet or Coerulein and an excess of chrome mordant, or consisting of chrome mordant alone, thickened with gum, is printed on cloth prepared with oleate of tin, and then another colour containing Gallein and acetate of chrome insufficient in quantity to completely fix it, printed partly over the first colour, a fine dark "conversion" shade is produced, where the two colours come in contact. The colour consisting of chrome mordant without colouring matter, washes away, except where the second colour covers it. The following examples of the composition of such colours are given:—

Medium Violet.—1 litre of Gallein paste; 200 grms. of acetic acid, 12 Tw. Dissolve and add:—1 litre of gum senegal solution (1 kilo. per litre); 55 grms. of acetate of chrome, 15 Tw.

Conversion Violet.—2 parts of Medium violet; 4 parts of gum senegal solution.

From these results it appears that the quantity of chrome mordant necessary to fix a certain quantity of Gallein must be very closely regulated. Shades obtained from printed colours, with a constant quantity of Gallein, but a variable amount of chrome mordant, differed considerably both in appearance and fastness. It is, further, to be noted that, in reducing a dark colour with gum solution or starch paste, an addition of chrome mordant is necessary. Such a reducing mixture as the following should be used.

Gum Solution for Reducing.—3 litres of gum senegal solution (750 grms. per litre); 300 grms. of acetate of chrome, 28 Tw.—E. R.

Report on Lamy's Conversion Colours. M. Mattauoh. Bull. Soc. Ind. Rouen, 1888, 283—284.

SUBSEQUENT experience has fully confirmed Lamy's opinion regarding the necessity for the exact regulation of the quantity of mordant required to fix Gallein, so as to give at once the brightest and fastest shade. This exactness is also required by other colouring matters, especially by Alizarin, Nitroalizarin, and Alizarin-blue. Too little mordant gives a weak shade; too much renders it dull and

poor. This property of the colouring matters of requiring a definite amount of mordant may serve as a means of testing mordants. An example was given by Reher at the previous meeting of the Society. A series of colours, made with excess of alizarin and the samples of acetate of chrome, *e.g.*, to be tested, are printed, steamed and strongly soaped. The fullest shade is obtained from that sample of acetate of chrome which contains most oxide of chrome in a state capable of combining with colouring matters.

The principle of Lamy's conversion style was tried with some of the new colouring matters. The best results were obtained by first printing the colours containing an insufficiency of chrome mordant along with Alizarin blue S. or Coerulein S., and then printing, across them, the colours containing an excess of chrome mordant with Nitroalizarin and Coerulein, Alizarin-black, Coerulein, and Persian berries, or even the chrome mordant alone, suitably thickened, finally steaming and soaping as usual.—E. R.

PATENT.

Improvement in Indelible Ink. C. P. Dimitry, New Orleans, U.S.A. Eng. Pat. 648, January 16, 1888. 6d.

BICHROMATE of potash is dissolved in water, gelatin, also in solution, added, and the whole warmed and allowed to stand in the sunlight for half an hour. "Black aniline powder" dissolved in water is then added, and, after standing and straining, if necessary, a few drops of creosote. The inventor claims that the ink is non-rusting, non-corrosive, and acid and water resisting.—S. G. R.

VII.—ACIDS, ALKALIS, AND SALTS.

On the Constitution of Solutions. F. Rüdorff. Ber. 21, 3044—3050.

THE character of salts and double salts is determined by the acid which is combined with the base. The following experiments on the diffusion of various double salts are, therefore, grouped according to the acids which they contain. It may be premised that the absolute purity of double salts is a *sine qua non* for experiments of diffusion, as the smallest impurity greatly interferes with the result. For the purposes of the experiment, 100 cc. of the solution are subjected to diffusion with 600 cc. of water. The double salts of sulphuric acid yield the following figures:—

	Amount of Salt in 100 Grms. of Water.	Duration of Experiment in Hours.	Per 100 Grms. of Heavy Metal thereare	
			In the Diffusate.	In the Salt.
$K_2SO_4 + CuSO_4 + 6 H_2O$	10	3	268.0	122.4 K
$K_2SO_4 + NiSO_4 + 6 H_2O$	10	12	299.0	133.0 K
$K_2SO_4 + MnSO_4 + 6 H_2O$	10	12	509.0	142.3 K
$(NH_4)_2SO_4 + CuSO_4 + 6 H_2O$	20	3	136.0	56.9 NH_4
$(NH_4)_2SO_4 + MgSO_4 + 6 H_2O$	10	3	124.0	150.0 NH_4
$(NH_4)_2SO_4 + MnSO_4 + 6 H_2O$	15	0.5	188.0	65.7 NH_4
$(NH_4)_2SO_4 + CdSO_4 + 6 H_2O$	12	3	71.4	32.1 NH_4
$K_2SO_4 + Cr_2(SO_4)_3 + 24 H_2O$	15	6	149.0	50.9 K
$(NH_4)_2SO_4 + Fe_2(SO_4)_3 + 24 H_2O$	12	3	102.8	32.2 NH_4

The comparison of the two last columns clearly proves that the sulphate double salts are decomposed into the single salts by diffusion. If bisulphates be subjected to diffusion, they are decomposed into the neutral salt and the free acid. The double salts of oxalic and tartaric acids yield this result :—

	Amount of Salt in 100 Grms. of Water.	Duration of Experiment in Hours.	Per 100 Grms. of Heavy Metal there are	
			In the Diffusate.	In the Salt.
$3 \text{K}_2\text{C}_2\text{O}_4 + \text{Fe}_2(\text{C}_2\text{O}_4)_3 + 6 \text{H}_2\text{O}$	10	6	208·8	208·8 K
$3 \text{Na}_2\text{C}_2\text{O}_4 + \text{Fe}_2(\text{C}_2\text{O}_4)_3 + 6 \text{H}_2\text{O}$	15	6	122·5	123·2 Na
$3 \text{K}_2\text{C}_2\text{O}_4 + \text{Cr}_2(\text{C}_2\text{O}_4)_3 + 6 \text{H}_2\text{O}$	12	8	222·2	222·8 K
$\text{NH}_4\text{HC}_2\text{O}_4 + \text{H}_2\text{O}$	6	1	250·0	253·0 Free $\text{C}_2\text{O}_4\text{H}_2$
$\text{NH}_4\text{HC}_2\text{O}_4 + \text{C}_2\text{O}_4\text{H}_2 + 2 \text{H}_2\text{O}$	10	1	919·0	750·0 Free $\text{C}_2\text{O}_4\text{H}_2$
$\text{NaHC}_2\text{O}_4 + \text{H}_2\text{O}$	6	6	Per 100 grms. of Free Acid, 31·0 30·6 Na	
$2 \text{K}(\text{SO}_4)\text{C}_4\text{H}_4\text{O}_6 + \text{H}_2\text{O}$	6	3	Per 100 grms. of Antimony. 32·8 32·5 K	

These figures show that the salts under examination are not decomposed into their single salts, but remain in their solution as molecular compounds, with the exception of the ammonium peroxalate, which splits up into bioxalate and free oxalic acid. There exist only few double salts of chromic acid suitable for experiments of diffusion. Certain handbooks state that a solution of potassium chromate

yields crystals of bichromate in the first instance, and crystals of chromate of potash in the second instance. If this be so, it is to be expected that potassium chromate will be decomposed by diffusion. However, this statement is not borne out by the facts, as is easily proved by direct experiments with solutions of the pure salt; nor does a decomposition take place by diffusion.

	Amount of Salt in 100 Grms. of Water	Duration of Experiment in Hours.	Per 100 Grms. of Heavy Metal there are	
			In the Diffusate.	In the Salt.
K_2CrO_4	12	5	149·3	148·6 CrO_4
$\text{K}_2\text{Cr}_2\text{O}_7$	10	5	74·3	74·2 CrO_4
$\text{Na}_2\text{Cr}_2\text{O}_7$	15	2	44·7	43·8 CrO_4
$(\text{NH}_4)_2\text{CrO}_4 + \text{MgCrO}_4 + 6 \text{H}_2\text{O}$	10	3	Per 100 grms. of Magnesium. 320·0 166·6 NH_4	

Potassium and sodium bichromate are not decomposed by diffusion, whereas the double salt of ammonium magnesium chromate behaves similarly to the sulphate double salts. The result of experiments with double chlorides and cyanides is very interesting :—

	Amount of Salt in 100 Grms. of Water.	Duration of Experiment in Hours.	Per 100 Grms. of Heavy Metal there are	
			In the Diffusate.	In the Salt.
$2 \text{KCl} + \text{CuCl}_2 + 2 \text{H}_2\text{O}$	16	5	206·0	122·9 K
$2 \text{NH}_4\text{Cl} + \text{CuCl}_2 + 2 \text{H}_2\text{O}$	15	6	148·9	56·9 NH_4
$2 \text{KCl} + \text{ZnCl}_2 + \text{H}_2\text{O}$	12	6	294·6	120·2 K
$\text{KCl} + \text{MgCl}_2 + 6 \text{H}_2\text{O}$	12	6	120·0	162·8 K
$2 \text{NaCl} + \text{CdCl}_2 + 3 \text{H}_2\text{O}$	12	6	98·0	41·2 Na
$\text{BaCl}_2 + \text{CdCl}_2 + 4 \text{H}_2\text{O}$	10	5	53·9	122·5 Ba
$\text{KCl} + \text{HgCy}_2$	15	6	30·2	19·6 K
$2 \text{NaCl} + \text{PtCl}_4 + 8 \text{H}_2\text{O}$	12	2	24·1	23·7 Na
$2 \text{KCl} + \text{PtCl}_4$	10	3	41·9	40·1 K
$2 \text{NH}_4\text{Cl} + \text{HgCl}_2$	10	5	18·7	18·1 NH_4
$\text{KCy} + \text{AgCy}$	8	3	36·5	36·2 K
$2 \text{KCy} + \text{HgCy}_2$	10	6	39·4	39·03 K
$2 \text{KCy} + \text{NiCy}_2$	12	6	130·4	133·0 K
$2 \text{KCy} + \text{CdCy}_2$	15	6	69·8	69·9 K
$6 \text{KCy} + \text{Cu}_2\text{Cy}_2$	10	6	184·3	185·0 K
$\text{BaCy}_2 + \text{PtCy}_2 + 4 \text{H}_2\text{O}$	5	4	70·4	70·4 Ba

Whereas the first six chlorides and the potassium chloride-mercury cyanide are split up into their single constituents, the other double chlorides and all the double cyanides enter into solution as molecular compounds. The first seven salts are double salts, in the strict sense of the term,

whereas the rest may be designated as binary compounds, and, consequently, the sodium-platinum chloride, for instance, should always be expressed by the formula Na_2PtCl_6 (and not 2NaCl.PtCl_4). The result of the diffusion of the three sodium phosphates is thus:—

	Amount of Salt in 100 Grms. of Water.	Duration of Experiment in Hours.	Per 100 Grms. of Sodium there are	
			In the Diffusate.	In the Salt.
NaH_2PO_4	10	3	135.5	131.6 P
Na_2HPO_4	10	3	66.6	67.3 P
Na_3PO_4	10	3	33.0	44.9 P

The mono-sodium and di-sodium phosphate are not altered by diffusion, whereas the tri-sodium phosphate is split up. The corresponding three salts of citric acid are not decomposed, as shown:—

	Amount of Salt in 100 Grms. of Water.	Duration of Experiment in Hours.	Per 100 Grms. of Acid there are	
			In the Diffusate.	In the Salt.
$\text{Na}_3\text{HC}_6\text{H}_5\text{O}_7 + \text{H}_2\text{O}$	12	3	63.1	65.8
$\text{NaH}_2\text{C}_6\text{H}_5\text{O}_7 + \text{H}_2\text{O}$	12	4	16.9	16.4

A. Thomsen considers phosphoric acid a di-basic acid owing to its thermo-chemical behaviour, and for the same reason, designates citric acid as tri-basic. This view receives confirmation from the behaviour of the solutions of their respective salts.—S. H.

PATENTS.

Improvements in the Manufacture of Alkaline Carbonates. W. W. Staveley, Pontretract. Eng. Pat. 17,657, December 23, 1887. 6d.

CRUDE phenols from coal-tar oils or blast-furnace or coke-oven oils are agitated with milk of lime, whereby a solution of calcium phenate and cresylate, &c. is formed. This is treated with a solution of sulphate of sodium or potassium, and as a result calcium sulphate is precipitated, while sodium or potassium phenate remains in solution. After filtration, the solution of the phenate is subjected to a current of carbonic acid—lime kiln or flue gases—when the solution is decomposed with the formation of sodium or potassium carbonate, with some bicarbonate, and free phenol. On discontinuing the action of the gas, the mass is allowed to stand for some hours, when it separates into two layers, the upper one consisting chiefly of phenol, whilst the lower one consists of a solution of carbonate. The supernatant layer is separated and used again in the first stage of the process, whilst the solution of carbonate, which, however, still contains from 1 to 2 per cent. of phenol, is worked up for sodium or potassium carbonate.

—S. H.

Improvements in separating Arsenic from Hydrochloric Acid. M. N. d'Andria, Salford. Eng. Pat. 17,908, December 30, 1887. 4d.

This invention consists in precipitating the arsenic as sulphide by adding to the crude hydrochloric acid precipitated zinc sulphide, preferably in the damp state.

—S. H.

Improvements in Treating Liquid Acid Residues from Galvanising Works to obtain Products therefrom. M. N. d'Andria, Salford. Eng. Pat. 17,909, December 30, 1887. 6d.

See under X., page 52.

Improvements in the Manufacture of Sodium Bicarbonate, and in Apparatus therefor. E. Solvay, Brussels. Eng. Pat. 173, January 4, 1888. 8d.

The object of this invention is the purification of the crude sodium bicarbonate obtained in the ammonia-soda process. For this purpose the crude bicarbonate is dissolved in water,

or in the mother-liquor from a previous operation, by the application of heat; after filtering and cooling, the solution is treated with carbonic acid. Commercially pure bicarbonate is precipitated, which is separated and only requires finishing to be ready for use. The apparatus employed consists of a vertical column *a*, provided at the top with an inlet *b* for the introduction of the crude bicarbonate, and at the bottom with a pipe *c* for the admission of steam. Near the top is a pipe *d* for the admission of water or mother-liquor from previous operations. *f* is a pipe through which the gases resulting from the decomposition of the bicarbonate pass out to enter a refrigerator *g*, and afterwards a washer *h*. The purified gases are then taken into the

bottom of a second column *k*, in which the bicarbonate is reproduced. The liquor drawn off from the bottom of column *a* passes through a pipe *d*, thence through a filter (not shown in the drawing), and is introduced into a cooling drum *m*, whence it is conveyed to the top of column *k*. Here it is treated with the carbonic acid introduced at the bottom through *i*, and the bicarbonate thus produced is drawn off at *p* on to a filter bed. The mother-liquor from the column *k* is forced by a pump through pipe *e* into the refrigerator *n*, and after passing round the pipes is conveyed to the top of column *a*. The refrigerator *n* is thus used both for cooling the liquors obtained in the first operation, and heating those for dissolving the crude bicarbonate.—S. H.

Improvements in and Apparatus for or connected with the Production of Oxygen and Nitrogen Gases from Atmospheric Air. E. B. Ellice-Clark and L. Chapman, Westminster. Eng. Pat. 1844, February 7, 1888. 8d.

In this invention an improvement is contemplated in apparatus as made under a previous patent granted to Messrs. Brin (Eng. Pat. 157, of 1885), the object being to effect the separation of moisture from the air, previous to its being admitted to the retorts containing the anhydrous oxide of baryta, in a more efficient and economical manner than hitherto.

For that purpose the air is first compressed and then cooled, with the result of depositing its moisture as water, which is drawn off. The air is then allowed to expand whilst doing work, whereby the residue of moisture is further deposited and got rid of in the form of snow, at the same time that part of the power used for compression is recovered. The dry air is then heated to the required degree on its passage to the retorts, where it is used as prescribed in the previous patent. The specification is accompanied by a drawing showing one arrangement of the compressing, cooling, and re-expanding apparatus.—B.

Improvements in treating Sulphate of Lime and other Oxidised Sulphur Compounds of Calcium to obtain Sulphuretted Hydrogen, and in Apparatus employed therein. A. M. and J. F. Chance, Oldbury. Eng. Pat. 2495, February 20, 1888. 6d.

SULPHATE of lime or other oxidised sulphur compound of calcium is converted into the sulphide by heating with carbonaceous matter. The sulphide is then ground with water to a thin cream and placed in suitable closed vessels furnished with inlet and outlet pipes and taps. A current of the gases from a closed limekiln, consisting almost entirely of carbon dioxide gas and nitrogen, is then passed through the mixture. Calcium carbonate is precipitated in the first vessels, and the sulphuretted hydrogen liberated passes on to the next vessels, where it forms calcium sulphhydrate. When sulphuretted hydrogen is beginning to issue from the last vessel in the series the outlet tap from one of the intermediate vessels is opened and the issuing gas conducted away, preferably to a gas holder. The gas so obtained contains a large percentage of sulphuretted hydrogen, because by the action of the carbonic gas on the sulphhydrate two equivalents of sulphuretted hydrogen are evolved per equivalent of carbon dioxide absorbed, whereas by the action of carbon dioxide on the sulphide only one equivalent of sulphuretted hydrogen is given off per equivalent of carbon dioxide employed. (See Eng. Pat., 8666 of 1887, this Journal, 1888, 210.)

—S. G. R.

Improvements in Apparatus for the Production of Chlorine. J. A. Just, Syracuse, U.S.A. Eng. Pat. 14,857, October 16, 1888. 8d.

Improvements relating to the Production of Chlorine. J. A. Just, Syracuse, U.S.A. Eng. Pat. 14,859, October 16, 1888. 8d.

This chlorine process is based on the action of a mixture of nitric acid and hydrochloric acid on manganese peroxide.

Fig. 1.

Fig. 2.

Fig. 3.

The product of the reaction is afterwards treated in such a manner that manganese peroxide and nitric acid are recovered in order to be used over and over again. The apparatus employed consists of a large number of earthenware stills (Fig. 2), arranged in a battery, as seen in Fig. 1. The stills are charged with the acid mixture and manganese peroxide, and being placed in a bath of calcium chloride solution the outward application of heat soon gives rise to an evolution of chlorine gas. The latter is washed and dried and then passes on to chloride of lime chambers. It is usually found that chlorine forms a hard and thick superficial crust on the lime, which crust prevents or at least impedes the further absorption of chlorine. The inventor prevents the formation of this hard crust by mixing the chlorine gas before it reaches the chambers with from 20 to 35 per cent. of air. When the charge in the still is exhausted, the liquid contents, consisting mainly of manganous nitrate, is run off by means of a syphon into a well, whence it is ultimately pumped into a pan k^1 (Fig. 3), for the recovery of manganese and nitric acid. This pan is very gradually heated until a solid residue of manganese nitrate is left behind. This residue is then strongly heated in order to completely decompose it, that is to say, until the residue consists of pure manganese peroxide, which is used in freshly charging the stills. The gases and vapours given off during this decomposition are made to ascend a tower k^2 , through which they rise in a zig-zag course to the top, a pipe, k^1 , at the bottom admitting atmospheric air to mingle with the vapours. On their course they meet with a spray of water, which is introduced at the top of the tower and serves to condense the vapours as they ascend. The solution of condensed vapours so formed is carried off to the last jar of a series, whence it circulates backwards towards the first jar, in the opposite direction pursued by the vapours still uncondensed. These latter pass from the tower through a cooler n^1 to a series of jars m^1 to m^8 , and finally up a second tower o^1 , where they are effectually condensed. The strongest acid collects in the first jar m^1 , whence it is drawn off to supply the stills. By working the stills in a system the whole process becomes continuous.

—S. H.

(For Figs. 1, 2, and 3, see pages 46 and 47.)

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Portland Cement Mortars and their Decomposition by Sea Water. Engineer, 66, 386.

DURAND-CLAYE and Paul Debray have published in the *Annales des Ponts et Chaussées* a memoir on the permeability of Portland cement mortars, and their decomposition under the action of sea water. Until lately, they state, it was too readily admitted that if Portland cement mortars were not completely impervious to sea water, they were at least unaffected by its destructive action until after a long period, and then only in a partial measure. But divers accidents have occurred lately which show that, in order to protect works exposed to the sea from destructive eventualities, it is at all times necessary to take very minute precautions in the composition of Portland cement mortars, as well as in those of hydraulic lime, and to exercise great care in employing them for masonry work.

On the invitation of the Commissioners for experimenting in cements, these engineers proceeded to analyse numerous samples gathered together by local engineers, and endeavoured to explain, by means of laboratory experiments, the accidents to which they are liable:—

Proportion of		Ratio of the Weight of Magnesia to the Total Weight of the Lime and Magnesia.	Sulphuric Acid.
Magnesia.	Lime.		
0.25	13.05	0.02	0.05
0.20	13.30	0.01	0.10
0.25	11.49	0.02	0.50
0.30	10.35	0.03	0.05
0.35	9.75	0.03	0.05
1.60	8.50	0.16	0.30
0.10	10.20	0.01	0.45
0.19	10.10	0.01	0.40
0.45	11.45	0.04	0.60
2.90	5.30	0.33	0.60
3.90	4.70	0.45	0.40
0.35	11.90	0.03	0.95
0.10	9.95	0.01	0.35
0.25	11.35	0.02	0.40
2.70	6.15	0.30	0.60

It is important then that the results of this examination should be known to all constructors.

1. *Analysis of the Samples.*—The preceding table gives the results of the analysis of the samples of sand concrete applied to an equal hypothetical section of quay wall, and classed in this section, descending from the summit to the foundations. This table shows that the proportions of magnesia and sulphuric acid are very variable in the different samples, which can only be explained by the action of the sea water on the basin. The samples containing the largest quantities of magnesia or sulphuric acid correspond to those parts of the quay walls which have been the most damaged. The next table gives the analysis of the mortars extracted from the joints of the masonry of the docks in the places where the cracks were widest.

Proportion of		Relation of Weight of Magnesia to combined Weight of Lime and Magnesia.	Quantity of Sulphuric Acid.
Magnesia.	Lime.		
3.50	7.65	0.31	1.10
2.70	8.45	0.24	0.85
1.65	8.05	0.17	1.20
1.50	6.85	0.20	1.55
7.80	10.20	0.43	0.40
1.05	7.40	0.35	1.00

These results show that, in this case as in the preceding, the Portland cement mortars have been greatly affected by the sea water.

2. *Experiments on the Permeability of the Mortars.*—The experimenters acting on sand samples taken from the upper parts of the works, or from the walls of docks which had not been exposed to sea water, stated that the sand concretes and mortars were not only very porous but very permeable. It should be observed that porosity is the faculty which mortars, that have been exposed to the air, have of absorbing a certain quantity of water when they are immersed in basins and there left for a sufficient length of time; while permeability is the faculty which blocks of mortar may have of allowing a certain quantity of water to

pass through them when one of their sides has been submitted to the action of a charge of water. In order to test the degree of porosity of a mortar, it is sufficient to take a certain quantity of this mortar, to weigh it, either immediately or after having left it for a certain time in a sand-bath heated to a moderate temperature; a weight P is thus obtained. The same sample weighed after complete imbibition gives a weight P^2 , greater than P . The porosity

of the sample is measured by the fraction $\frac{P^2 - P}{P}$, which represents the proportionate increase to the weight of the mortar resulting from the absorption of a certain quantity of water which has been able to penetrate into its pores, filling the spaces previously occupied by air. As to permeability, it may be measured, all other things being equal, by the quantity of water which passes through in a given time.

After having satisfied themselves that the samples of concrete and mortar, presented to them as liable to decomposition under the action of sea water, were permeable, the experimenters produced the same effects by substituting solutions of salts of magnesia for sea water. The strength of the sulphate of magnesia was reduced to 6 per 1,000 in order to equalise the quantity of this salt to the proportion of it which exists in sea water, that the decomposition of the blocks might not be exaggerated. The sand concretes made with divers cements—French, English, and Belgian—were therefore tried, and the same results obtained from all; only that the decomposition took place in different parts with more or less rapidity, according to the copiousness of the filtrations.

Durand-Claye and Debray proceeded to test the filtrations in the following way. They made some truncated cones of mortar, 4 centimetres high, 5 centimetres in diameter at the base, and 4·5 at the smaller end. To the bases of the cones, turned upwards, they attached long glass tubes, uniting the glasses to the cones by means of pure cement. They made thus four series of three cones of the following mixtures:—

- (a) 200 kilos. of cement, 200 kilos. of water to 1 me. of water.
 (b) 200 " " 150 " " 1 " sand.
 (c) 350 " " 200 " " 1 " "
 350 " " 150 " " 1 " "

In each series the cones were first submitted to filtrations of pure water; secondly, to water charged with sulphate of magnesia, in a proportion of 6 per cent.; and, thirdly, to water charged with sulphate of magnesia, in a proportion of 30 per cent. The mortars being very permeable, the glasses had only to be filled to obtain sufficiently copious filtrations. These experiments lasted about 25 days.

It was stated generally that the cones of mortar through which the water charged with sulphate of magnesia had passed were more fissured when the proportion of cement mixed with the mortar was large than when small and the quantity of water employed small, and that the water filtered through was more impregnated with sulphate of magnesia. The analysis of these cones has led to the following conclusions:—(1.) The filtration of pure water had carried off a certain proportion of the lime existing in the mortars and proceeding from the cements. (2.) Under the action of the waters charged with sulphate of magnesia, a part of the lime contained in the mortars disappeared, while the proportion of magnesia and the quantity of sulphuric acid increased. This system of experiment was afterwards abandoned, as it appeared inadvisable to introduce beside the mortars a covering of cement, itself subject to the influences of a nature to disguise the results sought for.

The experiments showed that whatever the nature of the filtering waters was, the filtrations, which were sometimes very abundant at first, diminished rapidly in quantity, and at the end of a short time they became, if not actually *nil*, at least very feeble. But, at the same time, the mass of concrete became swollen.

From the results of these experiments it would appear that there is a certain quantity of water required for each kind of mortar, which corresponds to the maximum of capacity and the minimum of permeability of the mortars. This phenomenon explains itself naturally, if it be observed

that when the mortars are made the grains of cement are in the same state as the grains of sand. Now it is known that sand which is merely damp swells and occupies a greater volume than dry sand, and on the other hand, sinks considerably if any quantity of water is poured upon it. It is the same with the grains of cement; when the quantity of water is great, and the matter lumped together, as in the making of mortar, there remain relatively considerable distances between the grains.

Durand-Claye and Debray have also made a study of the comparative action of the solutions of sulphate of magnesia and chloride of magnesium, in the proportion of 6 per cent. in two series of five experiments, in a mixture of one of cement to four of sand and 10 per cent. of water, made separately, so as to eliminate as much as possible all other influences than those of the solutions employed. The samples submitted to the action of the solutions of sulphate of magnesia broke between the tenth and twentieth day of filtration, while the samples submitted to the chloride of magnesium resisted at least 60 days. The fractures of the samples tried by sulphate of magnesia were more numerous, and denoted that the action of the sulphate of magnesia was more powerful than that of the chloride of magnesium. The chemical analysis showed that the test pieces submitted to the action of sulphate of magnesia contained 0·75 to 0·80 per cent. of sulphuric acid. It is concluded from this that after the phenomenon of the double decomposition between the salts of lime and the sulphate of magnesia pointed out long ago by Vicat, a part of the sulphate of lime formed remains in the mass of mortar.

It is to this production of sulphate of lime that the experimenters attribute the phenomena of the breaking of the masonry composed of Portland cement mortar subject to the action of sea water. This analysis seems to show clearly that the lime produced by the action of the sea on the mortars is not entirely carried off by the water which circulates within the masonry walls, and that it plays an important part in the disintegration of the masonry. While the magnesia produced deposits itself in a state of milky cream, without consistency, unable to exercise any mechanical action on the masonry, the sulphate of lime is consolidated more or less completely into crystals of a nature to produce considerable disintegrating effects.

—W. S.

Composition of some very old Mortars. W. Fahrion. Gewerbebl. Grossh. Hessen, 1888, 361.

THE mortars in question came from some buildings which were built in the third century by the Romans. I. was plaster taken from the ceiling; II. plaster from the wall surrounding the structure; III. plaster from the walls of a cavity; IV. mortar. The analysis showed the following result:—

	I.	II.	III.	IV.
Moisture.....	0·97	1·32	2·41	1·55
Water, chemically combined.....	3·05	2·76	2·90	3·33
Sand (insoluble in HCl).....	73·62	77·02	64·17	76·71
CaCO ₃	12·18	8·41	15·68	5·78
MgCO ₃	0·38	0·12	1·24	1·14
CaSO ₄	0·07	0·32	0·37	0·37
CaO.....	1·21	0·97	2·27	1·39
Soluble silica.....	1·11	1·37	2·46	1·08
Al ₂ O ₃ + Fe ₂ O ₃	7·44	7·35	8·33	8·17
Cl and alkalis.....			Trace.	

The small amount of magnesia is very remarkable, as well as the large percentage of iron peroxide and alumina. The carbonic acid present is not sufficient to combine with magnesia and lime; a portion of the latter is present either as hydrate or silicate. The proportion of lime to sand is

always important for the physical properties of any mortar. In these samples the proportion of lime to sand is 1:8.86; 1:12.65; 1:5.33; 1:13.87 respectively. A good lime-mortar should contain from 13 to 15 per cent. of lime. All these mortars are deficient in lime, and owing to this circumstance the mortars are very brittle and devoid of firmness.—S. H.

Varieties of Clay and their distinguishing Qualities, for making Good Puddle. W. Gallon. Proc. Inst. Civil Engineers, 94, Part IV.

THE author describes generally the well-known physical characteristics of the chief varieties of clay, and broadly designates as clay "any substance formed of minute particles of decomposed earthy material which, when worked up with water, becomes plastic or capable of being moulded." Hydrated silicate of alumina imparts the plasticity characteristic to clay. Most kinds of clay when tempered are found suitable for puddle, and as the essential condition for this purpose is simply imperviousness to water, no special purity is requisite. The most important features of a good puddle clay are its cohesion and its power of retaining water. A sufficient test for the former is to form it by the hand into a roll about 1½ inches diameter and 12 inches long; when suspended by one end the cohesion should be sufficient to prevent fracture. To test the latter property, one to two cubic yards should be tempered by water and rendered plastic; a hollow formed in the centre of the mass should hold 4—5 gallons of water, which, if protected from evaporation, will be retained for 24 hours if the clay be good for the purpose. When used as puddle, clay should be protected against evaporation and consequent cracking; admixture with sand obviates cracking when evaporation cannot be wholly prevented.—C. C. H.

The Instability of Cements rich in Magnesia. From the Inspector, Dr. Böhme, by order of the Minister of Public Works, Berlin.

THE following observations on this subject had been made before the author instituted his experiments. Lechartier had observed instability in cements varying from 21.2 per cent. to 34.72 per cent. of magnesia. He ascribed it to the fact that magnesia combines with water to form a hydrate of great consistency and hardness, and this combination is accompanied by an increase in volume. In the case of cements this increase occurs after a longer time, when they have been burnt at a high temperature, and the change occurs more quickly when the water can act directly on them and penetrate their mass. With a tile 1 metre long, an increase of length of 0.04 metre was observed. The pressure accompanying this expansion was observed to be very great. Large blocks of granite were made to burst, and notable changes were caused in buildings.

Experiments made in the laboratory "de l'Ecole des ponts et chaussées" showed that the destruction of the arches of some bridges was due to cement rich in magnesia. Similar conclusions were arrived at by Hayter, a London engineer.

The following are analyses of the cements used in the assize courts and the principal church of Cassel, in which instability was observed:—

	(a.) Assize Courts.	(b.) Church in Cassel.
	Per Cent.	Per Cent.
Total silica	19.75	14.87
Oxide of iron and alumina	7.39	8.61
Lime	32.05	31.90
Magnesia	22.00	22.06
Loss on ignition	18.72	22.36
Total	99.91	99.77

The magnesia shown by these analyses is much higher than that in normal Portland cement. The magnesia in 32 different Portland cements analysed in the Royal Technical Experimental Station in Berlin varies between 0.47 per cent. and 2.89 per cent.

The following are analyses of cement taken from various places in the assize courts in Cassel:—

	(1.)	(2.)	(3.)	(4.)
	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Sand	3.34	12.07	4.65	45.90
Combined silica	11.41	11.14	13.15	7.12
Lime	32.00	29.67	30.43	15.59
Magnesia	21.96	19.56	21.38	10.80
Alumina	4.79	4.40	4.43	2.18
Oxide of iron	1.99	1.82	1.48	0.73
Alkalis	0.45	0.47	0.76	0.73
Carbonic acid	7.39	6.55	6.07	6.74
Sulphuric anhydride	0.98	1.17	0.93	0.66
Water	16.28	13.17	16.42	8.62

Results calculated on the cement free from sand:—

	(1.)	(2.)	(3.)	(4.)
	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Combined silica	11.75	12.67	13.83	13.39
Lime	32.97	33.75	32.02	29.33
Magnesia	22.62	22.24	22.49	20.51
Alumina	4.94	5.00	4.66	4.09
Oxide of iron	1.93	2.07	1.53	1.37
Alkalis	0.46	0.53	0.80	1.37
Carbonic acid	7.52	7.44	6.38	12.68
Sulphuric anhydride	1.01	1.23	0.99	1.24
Water	16.77	14.97	12.27	16.22

An Improved Composition for Fusible Cements. M. Mackay, London. Eng. Pat. 667, January 16, 1888. 4d.

THE cement, which is said to be unaffected by water, acids, and alkalis, to be hard, tough, cheap, and a good insulator, is made by heating together in a copper or iron vessel 3 parts of sulphur, 1 of silicate of magnesia (steatite preferred), and 2 of powdered fibrous asbestos. Any suitable proportion of powdered aluminium silicates or oxide, or slag, may be substituted for the steatite, but the asbestos is an essential constituent.

The proportions may be varied and pigments added if desired. A softer and more adhesive composition may be made by replacing a part of the sulphur by pitch, tar, rosin, or similar resinous or oleaginous matter, and may be used for coating iron pipes inside or outside, and may be applied to the joints of pipes or tanks, allowing as it does of greater expansion and contraction of the articles in question than the original mixture. A paint may also be prepared by adding to the cement a hot solution composed of 2 parts of "turpentine," $\frac{1}{8}$ part of rosin, and $\frac{1}{8}$ part of sulphur, all by weight. The proportions given above for all these mixtures may be varied if found necessary.—B. B.

Improved Fibrous Asphalt Composition for rendering Concrete Roofs, Railway Arches, Walls, and other Structures, Waterproof and Damp-proof, and in the Method of applying such Composition. J. Cliffe, Salford. Eng. Pat. 1294, January 28, 1888. 4d.

ABOUT equal parts of "Limmer rock asphalt, bitumen, sand, limestone, pitch, creosote oil, varnish, tar, cowhair, cotton and fibre waste," are mixed and heated until reduced to a condition of pulp; a layer about $\frac{3}{4}$ in. thick is then floated on the top of the roof or arch to be protected, and covered with sacking cloth, which is caused to adhere by the passage of a roller over the whole while the mixture is warm. A second layer of the composition ($\frac{1}{4}$ in. thick) is then applied, and also covered with sacking cloth, which is, however, laid this time across the first at an angle of 45° , and the roller used as before. A third layer of the composition ($\frac{1}{4}$ in. thick) is then run on and covered with sacking cloth at right angles to the second, and the whole is then completed with another layer of the composition about $\frac{1}{2}$ in. thick.—B. B.

Improvements in the Manufacture of Artificial Stone. W. E. Constable and J. Joseph, London. Eng. Pat. 2641, February 22, 1888. 4d.

LIMESTONE rock, "preferably that found in the county of Derbyshire," is broken into pieces of "about $\frac{3}{8}$ of an inch in size" in any convenient manner, and mixed with Portland cement and enough water to render the mass workable; it is then placed in moulds preferably made of wood lined with oiled steel, and of a shape suited for the use to which the stone is to be put. When set, the blocks of stone are removed from the moulds and placed in dilute sulphuric acid—1 part of acid to 99 parts of water being a suitable strength—in which they may remain for about 21 days. The stone is ready for use about a month after removal from the acid-bath.—B. B.

An Improved Cement or Artificial Stone. C. Waxin and A. Clerj, London. Eng. Pat. 11,750, October 13, 1888. 4d.

SEVENTY-FIVE parts of pulverised stone are mixed with $12\frac{1}{2}$ parts of zinc oxide and $12\frac{1}{2}$ of magnesia; 7 parts of zinc, 5 of borax, and 5 of sal-ammoniac, are then dissolved in 83 of muriatic acid. The two preparations are then mixed in such proportions that the resulting compound may be poured into moulds or be applied with a brush, a suitable ratio for many purposes being 70 parts of the first to 30 of the second. However used the mass speedily becomes hard. If it be desired to imitate any particular stone, that stone, in powder, is used as a basis. When a very hard artificial stone is to be produced the quantities of oxide of zinc and magnesia in the solid compound mentioned above may be increased by 10 or 20 parts, the quantity of pulverised stone being correspondingly reduced, while at the same time the proportions of zinc, borax, and sal-ammoniac in the liquid mixture may be augmented by 5 or 10 parts at the expense of the quantity of muriatic acid used. Alteration of the mixture in the reverse direction will produce a softer stone. The stone may be coloured, or a marbled appearance given to it, by the use of any suitable pigment, which, if solid, may preferably be added to the solid portion of the ingredients, and if liquid, to the liquid part. While setting, the stone may, if desired, be subjected to pressure in any convenient manner.—B. B.

The Effect of Rolling and of Wire Drawing upon Mild Steel. H. Allen. Proc. Inst. Civil Engineers, 94, Part IV.

IN this paper the author describes experiments made in order to verify the statements commonly published that the manipulation of mild steel during its formation into wire increases its tensile strength. Specimens were prepared by reducing billets 2 ins. square by hot rolling to rods of various sizes, and subsequently to wires of various thickness, by cold drawing, in the usual manner. The author finds, in the first case, that the elastic limit is raised in some instances as much as 47 per cent., the breaking stress by about 14 per cent., the reduction of area at the point of fracture being increased by about 25 per cent., and the elongation diminished by about 34 per cent. The specific gravity is also increased by the hot rolling, which may be slightly diminished by subsequent reheating and cooling. Cold drawing of the rods into wire appears to have even a more marked effect in the same direction as in the case of the rods obtained by hot rolling. The paper is illustrated by diagrams showing graphically the physical changes produced, and also comprehensive tables showing the results yielded by the large number of experiments made.—C. C. H.

Water Oil Gas in the Steel Furnace. Engineer, 66, 324.

ARCHER'S patent process for using water oil gas for steel conversion is now used at the Barrow Steel Works, Barrow-in-Furness. The object of the patent is twofold—the reduction of cost, and the complete prevention of the admixture of dust or any foreign substance with the steel in the course of manufacture. The oil used is the coal-tar creosote of commerce in its unpurified state. This is kept in a store tank outside the works, which may be buried in the ground and entirely removed from all risk of fire. From this tank the oil is pumped, and then propelled through tubes, which are surrounded by gas-produced fire. In its passage the oil is converted into gas, and as it leaves the converter—which is a compact brick stack, about 10 ft. by 8 ft. and 8 ft. high—it mixes with superheated steam from the ordinary works boiler or from a small boiler for the purpose. At Barrow a small boiler was used, and the steam was at 80 lbs. in the boiler, and at about 50 lbs. when it entered the converting stack. After reaching this stack it passes through coils of copper pipe, and is raised to a temperature of about 2,000° Fah. The water is by this process decomposed, and the gases produced unite in their passage to the steel furnace—with the creosote gas, the combined gases passing on to the furnace through a 2-in. pipe. The supply conveyed by this pipe is sufficient to feed two steel furnaces with all the fuel they require, the gases being brought into the furnace by the suction of the chimney, and not by pressure from behind. The combined gases were admitted into the furnace in precisely the same manner as in the Siemens gas furnace; in fact, through the same tubes that had been used in the Siemens process, the difference between the small tubes required for Archer's process and the large ones previously used being very striking. The combustion in the furnace was perfect, and the heat obtained very intense. No alteration of the furnace is required in the adoption of Archer's water and oil gas, so that no expense is incurred beyond the actual cost of the conversion stack, which is a small and simple affair. Nor is it liable, as is the case in many fuel-saving processes, to get out of order, and be expensive in repairs. The supplies of the decomposed steam and the oil gas are regulated by valves, under the control of the one man who has charge of the converter. One important claim made by the patentee is, that in the use of water oil gas as a fuel for steel production, a portion of the sulphur is eliminated from the steel. This has been proved, it is said, by repeated trials and analysis; and although all the sulphur is not removed, this fact considerably enhances the value of the process, other

things being equal. In point of cleanliness nothing could be more satisfactory. The oil cost $1\frac{1}{2}d.$ per gallon, and 25 to 30 gallons of oil will produce one ton of finished steel from the furnace.—W. S.

Some curious Properties of Metals and Alloys. W. C. Roberts-Austen, Roy. Inst. Gr. Britain, and Iron, November 23, 1888, 462.

ALTHOUGH the importance of the isomeric and allotropic states was abundantly recognised in organic chemistry, it had been much neglected in the case of metals. Joule and Lyon Playfair showed, in 1846, that metals in different allotropic states possess different atomic volumes, and Matthiessen, in 1860, was led to the view that in certain cases when metals were alloyed they passed into allotropic states, probably the most important generalisation which has as yet been made in connexion with the molecular constitution of alloys.

Instances of allotropy in pure metals are: Bolley's lead, which oxidises readily in air; Schützenberger's copper; Fritzsche's tin, which falls to powder when exposed to an exceptionally cold winter; Gore's antimony; Graham's palladium, and allotropic nickel. Metals can be obtained in chemically active states under the following conditions:—Joule proved that when iron is released from its amalgam by distilling away the mercury, the metallic iron takes fire on exposure to air, and is therefore clearly different from ordinary iron, and is, in fact, an allotropic form of iron. Moissan has shown that similar effects are produced in the case of chromium and manganese, cobalt, and nickel, when released from their amalgams with mercury.

Evidence is not wanting of allotropy in metals released from solid alloys, as well as from fluid amalgams with mercury. Certain alloys may be viewed as solidified solutions, and when such bodies are treated with a suitable solvent, usually an acid, it often happens that one constituent metal is dissolved, and the other released in an insoluble form. A new alloy is one of potassium and gold, containing about 10 per cent. of the precious metal. If a fragment of this alloy be thrown upon water the potassium takes fire, decomposes the water, and the gold is released as a black powder; there is a form of this black or dark-brown gold which appears to be an allotropic modification of gold, as it combines with water to form auric hydride. By heating this dark gold to dull redness, it readily assumes the ordinary golden colour. The Japanese use this gold, released from gold-copper alloys, in a remarkable way, for they produce, by the aid of certain pickling solutions, a beautiful patina on copper which contains only 2 per cent. of gold, while even a trace of the latter metal is sufficient to alter the tint of the patina.

Prof. W. Spring, of Liège, has furnished much evidence in support of the view that polymerisation of metals—that is, the rearrangement of atoms in their molecules, can take place even in solid alloys of lead and tin.

With reference to the passage of metals into allotropic states under slight external influences, Debray has given a case of an alloy in which a simple elevation of temperature induces allotropic change in the constituent metals. It is prepared as follows:—Ninety-five parts of zinc are alloyed by fusion with five parts of rhodium, and the alloy is treated with hydrochloric acid, which dissolves away the bulk of the zinc, leaving a rich rhodium-zinc alloy, containing about 80 per cent. of rhodium. When this alloy is heated in vacuo to a temperature of $400^{\circ}C.$, a slight explosion takes place, but no gas is evolved, and the alloy is then insoluble in aqua regia, which dissolved it readily before the elevation of temperature caused it to change its state. We are thus presented with another undoubted case of isomerism in alloys, the unstable, soluble modification of the alloy being capable of passing into the insoluble form by a comparatively slight elevation of temperature.

Prof. Austen's own experiments have shown that very small amounts of metallic impurities exert an extraordinary

effect on the tenacity and extensibility of gold, and that, small as the amounts of these impurities are, their influence is rigidly controlled by the periodic law of Newlands and Mendeléef, the deleterious action of a metallic impurity being in direct relation to its atomic volume.—W. S.

PATENTS.

Improvements in or relating to the Chemical Treatment or Utilisation of Scrap Tin, or Terne Plates, Scrap Zinc, Galvanised Iron, and the like. A. S. Ramage, Liverpool. Eng. Pat. 16,604, December 2, 1887. 8d.

VARIOUS processes for stripping tin plate by the action of acids, and the recovery of the tin by means of zinc or lime, have been devised, but none of them yields the tin pure or the iron free from tin. The patentee's improvements are said to effect these and other desirable results. The tinned scrap is collected in cages, preferably of paraffined wood, one or more of which are placed in a truck and run under a travelling crane, by which they are lifted and lowered into troughs of enamelled iron, of wood soaked in paraffin, or of some other material unattacked by hydrochloric acid, with which liquid they are filled. (The hydrochloric acid has previously been freed from arsenic by treatment with a little of the liquor resulting from a former operation, which precipitates the arsenic as "arsenite of tin" (*sic*), by virtue of the stannous chloride it contains.)

The action of the acid on the scrap may be hastened by applying heat by means of steam coils, and circulation induced by giving an up-and-down motion to the cage. When the tin is nearly all dissolved off the iron, the cage is lifted and lowered into another tank of acid, and so on as often as may be necessary.

By thus working systematically the tin is completely removed (even the alloy of tin and iron, beneath the layer of tin being dissolved), and the acid is nearly completely exhausted.

After leaving the last tank the iron now remaining in the cage is washed with water, dried, and pressed into bales, in which state it can be sold for reworking, or for precipitating copper, for which purpose the ordinary loose scrap is not applicable. The saturated acid, consisting chiefly of a solution of stannous, ferrous, and lead chlorides, is run into a settling tank, and milk of lime added until nearly neutral; the lead is thus precipitated, and, after settling, the clear liquid run off, scrap zinc or galvanised iron added, and the whole heated by steam. The tin is precipitated and filtered off; being in a spongy state it can either be sold for making "tin crystals," or run down into ingots. In the latter case it must either be compressed before fusion, or melted without access of air, as the spongy metal is liable to oxidise largely during the process.

The mother-liquor of the tin is treated with milk of lime at a boiling temperature until the green ferrous hydrate begins to come down, by which time the zinc is nearly all precipitated, and can be filtered off, washed, and sold as zinc hydrate to alkali works, or dried and sold as zinc oxide. To the filtrate, milk of lime is added until all the iron is thrown down as ferrous hydrate, when it is filtered off, washed, and dried with occasional stirring, until it is converted into ferric oxide, when it is heated to dull redness, and then forms a red oxide pigment.

Among the claims appended to the patent is one for using the crude stannous chloride to precipitate the arsenic from the hydrochloric acid, whereby the tin recovered is obtained pure and tough, while the "arsenite of tin" is of commercial value, and can be sold as such, or roasted to stannic oxide, and the arsenic collected.—B. B.

Improvements in Treating Liquid Acid Residues from Galvanising Works to obtain Products therefrom. M. N. d'Andria, Salford. Eng. Pat. 17,909, December 30, 1887. 6d.

To the acid residues, consisting mainly of a solution of chloride of iron and free hydrochloric acid, is added magnesia or a mixture of magnesia and lime, obtained from calcined dolomite, until all the iron is precipitated. In

order to separate the oxide of iron more readily, either the solution is first concentrated and then diluted with water, when the iron oxide separates in a more dense condition, or air is blown through the mixture during the precipitation, thus forming peroxide of iron, which settles more readily. The ferric oxide is separated by means of either a filter press or centrifugal machine, and roasted to form pigment. To the solution of the mixed chlorides of lime and magnesium, magnesium sulphate is added, the calcium sulphate formed is removed, and the solution now containing only magnesium chloride is concentrated.—S. G. R.

Improvements in Recovering Tin from Tinned Metal.
M. N. d'Andria, Salford. Eng. Pat. 767, January 18, 1888. 4d.

The scrap tin plate is dipped in a bath of chloride of zinc heated to any convenient temperature above its fusing point. The tin is dissolved, and when present in sufficient quantity in the chloride of zinc, may be recovered therefrom by dissolving the mixture in water and treating with metallic zinc in the presence of a little hydrochloric acid. The tin is precipitated, and the solution of chloride of zinc concentrated, and used over again. As the activity of the chloride of zinc bath decreases by use, it may be revived at intervals by the addition of hydrochloric acid (introduced beneath its surface), or of "acid chloride of zinc." After washing, the recovered iron may be heated in a non-oxidising flame, and welded into thicker pieces for any suitable purpose.—B. B.

Improvements in the Production of Manganese Alloys.
O. M. Thowless, Newark, U.S.A. Eng. Pat. 13,830, September 25, 1888. 4d.

HITHERTO manganese alloys have been made by first reducing manganese from the black oxide, and then alloying it with the required metal, *e.g.*, copper, or by fusing ferro-manganese with a large quantity of wrought-iron scrap, and then adding the requisite amount of copper; if the ferro-manganese and copper were melted together directly, the product would be largely contaminated with iron.

The patentee claims that by his process alloys can be produced cheaply, and free from iron. Three parts of white sand, as free as possible from iron, are mixed with 10 of 65 per cent. ferro-manganese, 1 of cryolite and 10 of copper or other metal desired to be used, such as nickel or tin; the proportion may be varied according to the richness of the alloy that is to be made; the cryolite may be replaced by any other suitable flux. The mixture is fused in a crucible, or, on the large scale, in a blast furnace, when the alloy is produced and may be run off from the heavier slag. The action that takes place seems to be the removal of most of the iron by the sand and cryolite, leaving the manganese free to alloy with the other metal.—B. B.

An Improved Process for Amalgamating Gold by Volatilised Mercury. J. R. R. Yeats, Adelaide, S. Australia. Eng. Pat. 14,435, October 8, 1888. 6d.

THE finely-divided gold ore is fed through a hopper into a chamber, where it meets a hot blast of air from a Roots or other blower, which carries it in the form of dust over the surface of a pan of mercury kept heated by a furnace. Mixed with mercury vapour it passes on over a series of amalgamating tables, where it meets a cold blast of air or a stream of water, and on which the gold amalgam collects, and is removed from time to time.

It is claimed that by this means gold can be extracted that is usually lost by other processes.—B. B.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

Light Electric Battery for the Balloon "La France."
Dingl. Polyt. J. 270, 187—188.

RENARD has recently described some electric batteries used for balloon purposes. A bromine battery is the lightest that could be devised, but owing to its obvious disadvantages it was replaced by one in which the liquid is a solution of chromic acid in dilute HCl (11° B \acute{e}). This acts like a solution of chlorine. The best proportions of the two acids are their respective molecular weights. Such a battery will give about 5—6 times more electrical energy in the unit of time than that supplied by liquids employed in the bichromate batteries. The battery contains only this single liquid, and consists of a number of elements or "tube-shaped groups," provided with a cylindrical positive electrode, in the axis of which is a zinc pencil. In this manner the strength of the current is raised to 25—40 ampères on 100 sq. cm. Silver plates covered on each side with platinum are used as electrodes. It is better not to cover the zinc with amalgam. Foreign salts rapidly diminish the efficiency of the battery. The liquid is contained in ebonite or glass tubes, whose height is about ten times the diameter. With a normal tension of 1.2 volts the strength of the current is about 25 ampères on 100 sq. cm. at a temperature of 15° taken on the surface of the zinc.

The crystallised chromic acid may be replaced by the liquid obtained by mixing sodium bichromate with sulphuric acid. With a group of this balloon battery (two elements of six tubes) having a current of 100 ampères and 1.2 volts, Renard was able to melt iron wire of 2½ mm. diameter. The group weighed 10 kilos.—A. R.

PATENTS.

Improvements in Electrolysing Chlorides, Bromides, and Iodides, and in the Utilisation of the Products thereof.
W. Spilker, Berlin, Germany. Eng. Pat. 14,494, October 25, 1887. 8d.

A BATH is employed containing an inner porous compartment, the walls of the outer cell serving as the cathode. The inventor introduces some such body as lime into the liquid of the anode compartment, such body being a bad conductor of electricity, and being able at the same time to form a compound with the chlorine liberated, in the form of a hypochlorite, or, at higher temperatures, of chlorates and chlorides. In practice the inventor causes the solution—of potassium chloride for instance—saturated with the lime, to flow from a tank into the anode compartment, to flow thence by siphons into tanks, each at a lower level, containing lime to further saturate it, and thence to be pumped back again to the first tank; this goes on till the conversion is sufficiently complete.

The liquid in the cathode compartment consists at first of a 2 per cent. solution of potassium chloride, but a potash lye forms which flows over almost free from chloride into a special tank.

By using carbonates or bicarbonates "under chloric acid" is formed. The hypochlorites and the solution containing them may be used for bleaching purposes, and also for extracting metals, especially gold and silver, from their ores; the ores saturated with hydrochloric acid being treated with the solution, and the metals then extracted in the usual way. By adding alcohol to the anode compartment and closing in the latter, chloroform will be formed and may be distilled off; anthracene may also be treated for the production of "anthrachinone bisulphonate of lime," from which alizarin may be obtained chemically. The inventor also claims the method of depolarising the cathode by blowing air over its surface.—E. T.

Improvements in Primary and Secondary Galvanic Batteries. A. F. St. George, Red Hill, and C. R. Bonne, London. Eng. Pat. 16,296, November 26, 1887. 8d.

A positive electrode of tin surrounds a negative one of carbon, the space between being packed with meta-stannic hydrate, formed by the action of nitric acid on tin foil. The result of the battery action is the formation of tin or tin oxides; by keeping the cell constantly moist with nitric acid, the meta-stannic hydrate is reformed. The carbon is preferably made as a perforated hollow cylinder, nitric acid being introduced by a glass tube connecting the interior of the carbon with an outer vessel containing acid, or by dripping tubes and valves, or by capillary threads in connexion with a reservoir. Absorbent earth is sometimes mixed with the paste. For accumulators, both electrodes may be of tin, pasted with meta-stannic hydrate, and placed in dilute nitric acid. The fumes from the battery may be employed to act on tin fragments, and thus produce meta-stannic hydrate.—E. T.

Improvements in Secondary or Storage Batteries. H. Thame, London. Eng. Pat. 16,455, November 30, 1887. 6d.

THE inventor claims the use of plates made of uncured rubber or other vulcanisable material in which lead strips or dust are incorporated, the whole being then vulcanised. Projections can be left of rubber, &c., to act as separators, and also as feet, to raise the plates above the bottom of the cell. The plates are considered very suitable where cells are subjected to great vibration, as in tramears, &c.

—E. T.

An Improvement in Voltaic Batteries. E. Tyer, London. Eng. Pat. 39, January 27, 1888. 8d.

IN each cell are placed several groups of negative electrodes, each group being brought into action, in turn, by an automatic commutator. The electrodes have thus intervals given them for rest and to recover from polarisation.

—E. T.

Improvements in Electrical Accumulators. B. J. B. Mills, London. From J. Barbier, Villeurbanne, France. Eng. Pat. 13,984, September 28, 1888. 8d.

THE patentee subjects red lead, or other suitable salt, to electrolytic action, whereby either peroxide of lead or spongy lead is produced, with all the properties necessary for their use in accumulators. For a flat plate or slab, a framework is built up of lead—or it may be of some metal that will dissolve and ultimately disappear in the electrolyte—with horizontal strips running from side to side. The red lead to be converted is placed between the latter, and the whole made up into a thick plate. This is then treated electrolytically as an ordinary accumulator plate. By suitable frameworks, electrodes of any shape may be produced if desired. It is stated that such electrodes are electrically better, and do not crumble or lose their shape.

Further, by grinding up material thus formed, it may be moulded into solid plates of any desired form, metallic conductors being inserted during the process.—E. T.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

On Fish Oils. Heyerdahl. Chem. Zeit. 12, 1475—1476.

THE following substances were prepared from 400 kilos. of cod liver oil, extracted by steam: stearic acid having a constant melting point of 69° C., palmitic acid containing traces of other fatty acids, m.p. 62° C., oleic acid, glycerol, gaduin (formed by a secondary reaction from some substance still unknown), iodine to the extent of 0.0002 per cent., and traces of bromine. A portion, heated in a

current of CO₂, which was then led into hydrochloric acid, yielded trimethylamine, identified by means of its platinichloride. On a second experiment being made, none was obtained, so that it does not appear to be a constant characteristic product. Volatile acids were detected, but in extremely small quantity.

The influence of the length of time during which the livers were heated, on the proportion of free fatty acid in the resulting oil, was then made the subject of experiment. It was found that, contrary to expectation, the percentage of free fatty acid decreased slightly but perceptibly as the time of heating was increased (from 20 to 80 min.) and the temperature raised (from 62° to 85° C.). This effect might be due to the first portions of the extracted oil being richer in fatty acids, or to the presence of volatile fatty acids which were gradually driven off. To settle this point, measured volumes of air were driven through samples of oil heated on the water-bath, when it was found that the percentage of free fatty acid decreased up to a certain point, and then slowly rose to or beyond its original value. This accords with the second hypothesis. (In all these experiments the total amount of free fatty acid was small, never exceeding 0.7 per cent.)

To decide whether the rancidity of an oil depends on the quantity of free fatty acid it contains, a portion was saponified, the fatty acids separated and added in known proportion—from 2 per cent. downwards—to a sample free from rancidity. No rancid smell was perceptible in any case, and though the oil, to which 2 per cent. had been added, had a sharp taste, it was not of a rancid character. This was borne out by the samples already examined above, some of which were rancid and others not, and in which no connexion could be traced between rancidity and the proportion of free fatty acid. Rancidity appears to be produced by the action of air and on warming. Oil kept in well-closed vessels remains unaltered for years.

As a contrast to the oil obtained by steaming the livers, which contains less than 1 per cent. of free fatty acid, calculated as oleic acid, the following table shows the proportion present in oils obtained by the putrefactive process.

Kind of Oil.		Oleic Acid.
		Per Cent.
Crude medicinal oils:—		
Bright.....		3.79
Somewhat darker.....		3.87
Darkest.....		3.96
Commercial oils:—		
"Bright oil".....		10.9
"Brown oil".....		28.0
Other oils gave:—		
Source of Oil.		Oleic Acid.
		Per Cent.
Liver of <i>Gadus virens</i>		0.17
" <i>Brosmus Brosme</i>		0.08
" <i>Molea vulgaris</i>		4.36
" <i>Raja radiata</i>		4.80
" <i>Lamna cornubica</i>		2.62

They were all free from rancid smell or taste.

The method of determining free fatty acid used by the author is that devised by F. Hofmann. For this process 0.5—7.0 grms. of the oil are taken (according to the proportion of free fatty acid present), dissolved in 20—40 cc. of perfectly neutral ether, and titrated with caustic potash, using an alcoholic solution of rosolic acid (1 : 1,000) as an indicator.—B. B.

The Employment of Clay for Decolourising Paraffin Wax.
Veltrigs. Dingl. Polyt. J. 270, 182—186.

COMPARED with residues of yellow prussiate of potash which were hitherto used for the above purposes, clay, if finely powdered, is much more efficacious. The clay should be as white as possible, and since it acts the better the dryer it is, the fine powder must be heated to 300°—400° immediately before introducing it into the pan containing the molten paraffin, previously freed from water. Thus, a very finely powdered clay had 3—6 times the decolourising action of the agents hitherto employed; but this will not apply in practice, as it would not pay to reduce the clay to so fine a powder. Another advantage of using clay is that much less paraffin is retained in it than in other decolourising agents, and what is retained may be recovered more readily. Moreover, the paraffin filters better, probably owing to the heavy clay settling better in the molten paraffin. For ceresin this method is equally applicable, but it is not so satisfactory in the case of stearin.—A. R.

Presence of Glycollic and Propylenedicarbonic Acids in Suint. A. and F. Bušine. Compt. Rend. 107, 789—792. (Compare this Journal, 1888, 219.)

GLYCOLLIC acid ($\text{CH}_2(\text{OH})\text{CO}_2\text{OH}$) and propylenedicarbonic (pyrotartaric) acid ($\text{C}_3\text{H}_4(\text{CO}_2\text{OH})_2$), occur in the portion of the acids from suint, which is soluble in water, alcohol, and ether, and are left in solution when the malic acid, also present, is precipitated in the form of its barium salt. From this solution the acids are obtained free by treatment with sulphuric acid in excess and extraction with ether; they are then converted into lead salts, and the glycollic acid separated as basic lead glycolate, very sparingly soluble. The lead is removed by sulphuric acid, and the glycollic acid purified by conversion into its barium salt (when a little more malate deposits from the concentrated solution), and by the addition of a little sulphuric acid (much less than would decompose all the barium glycolate) which separates a small quantity of an oily acid which is still under investigation. The barium glycolate thus obtained gave 47.61 per cent. of barium instead of the theoretical 47.77 per cent. The free acid had all the properties of glycollic acid.

The lead salts soluble in water are then converted into the barium salts, and the removal of the small quantity of the unknown oily acid accompanying them, effected as described above, the treatment being repeated if necessary. The barium pyrotartrate is then crystallised from a concentrated solution (50 grms. in 70 cc. of hot water) and takes the form of silky radiating needles; the mother-liquor contains barium lactate. After recrystallisation the salt is found to have a composition corresponding with the formula $\text{C}_3\text{H}_2\text{O}_4\text{Ba} + 5 \text{H}_2\text{O}$. The free acid has all the properties of pyrotartaric acid.

These two acids exist in suint waters as the potassium salts; glycollic acid is one of the actual products of secretion, but it appears doubtful whether pyrotartaric acid is formed thus, or by oxidation of the fatty matter on the fleece. The proportions in which they occur in suint, average 1 per cent. of glycollic acid and 0.2 per cent. of pyrotartaric acid, on the dry residue.

Up to the present the following substances have been found among the products of sudorific secretion in suint: acids of the fatty series, from acetic to capric acid; two hydroxy-acids derived from the fatty series, viz., glycollic and lactic acids; two amido-acids from the same series, glycocine and leucine; three dibasic acids, oxalic, succinic, and normal pyrotartaric acids; one hydroxy-acid derived from the second of these, viz., malic acid; sundry others, e.g., hippuric, benzoic, and uric acids.—B. B.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

The Absorbing Capacity of Grey Vulcanised Caoutchouc for different Gases. G. Hütner. Ann. d. Phys. u. Chem. [N. F.] 34, 1.

(1.) BETWEEN the temperatures 5°—25° no constant coefficient of absorption of atmospheric air by grey vulcanised caoutchouc can be given. Any apparent absorption is due to the taking up of oxygen, which most probably serves to oxidise the caoutchouc.

(2.) Between the temperatures 15°—25°, no measurable quantities of nitrogen are absorbed by grey vulcanised caoutchouc.

(3.) Grey vulcanised caoutchouc absorbs about its own volume of dry carbonic anhydride at a temperature about 2° below zero. The coefficient of absorption diminishes with increase of temperature.

(4.) Between the temperatures - 2° and 13° no hydrogen is taken up by grey vulcanised caoutchouc; no absorption could be detected, even after three months' exposure to the gas.—H. T. P.

XV.—AGRICULTURE, MANURES, Etc.

Chemical Action of Superphosphate on Nitrate. A. Devarda. Bied. Centr. 17, 683—685.

THE author has investigated the question of the loss of nitrogen in mixtures of superphosphate and nitrate; he classifies the factors of destruction under three heads:—1. Those which set free nitric acid, such as free acids, and, perhaps, acid phosphates. 2. Those which convert nitric acid into nitric oxide, such as ferrous salts, easily decomposable organic matter, and ammonia. 3. Conditions favouring these decompositions, such as the temperature and moistness of the superphosphate.

Experiments were made at ordinary summer temperatures and at 50°, with mixtures of nitrate, in proportions corresponding to 2 and 4 per cent. of nitrogen, and bone-ash or animal charcoal superphosphate, containing, with added mineral phosphate, 18.48 per cent. of total, and 15.80 per cent. of soluble phosphoric acid, also with the same proportions of nitrate mixed with bone-meal superphosphate containing 18.13 per cent. of total, and 17.00 per cent. of soluble P_2O_5 , and in one case with ferrous sulphate corresponding to 1 per cent. of iron oxide. These mixtures were exposed, at ordinary temperatures, in sacks; at 50° in glass cylinders covered with linen. The nitrogen, the phosphoric acid, total and soluble, were determined both before and after the exposure and in some cases during the experiments. The quantity of soluble phosphoric acid remained unaltered, and the losses of nitrogen in the experiments at the ordinary temperatures were so small as to come within experimental error, showing that free acids, easily decomposable organic matter, &c. exert no deleterious influence at ordinary temperatures. At 50°, however, the case is different, and great losses of nitrogen (amounting even to $\frac{1}{2}$ per cent.) are observed, the losses being greater in the case of the bone-meal superphosphate than with the bone-ash or animal charcoal superphosphate; this is attributed to the readily decomposable organic matter, to greater proportions of free phosphoric acid, and probably also to the moist condition of the bone-meal superphosphate. The ferrous sulphate proved inactive in both series of experiments. Both the linen sacks and the covers of the glass cylinders were strongly attacked during the exposure by the free acids present; nitrous odours were observed in the cylinders. The bone-ash or animal charcoal superphosphate was dry and coarse-grained in character and evolved hydrofluoric acid on treatment with concentrated sulphuric acid.

From these results the author concludes:—1. That admixture of saltpetre with superphosphate should only be made in matured superphosphates. 2. That as far as loss of nitrogen is concerned such mixtures may be stored in sacks, even during the hot summer months.—D. A. L.

Experiments on the Estimation of Nitrogen in Soils.

Berthelot and G. André. *Compt. Rend.* **107**, 852—854.

These experiments were undertaken with the view of ascertaining what differences exist in the estimations of nitrogen in a soil, when they are made at different intervals of time, the soil being submitted to varying influences; also with the view of testing the stability of the nitrogen.

Three soils were kept at the ordinary temperature in an atmosphere free from nitrogen, to prevent possible absorption of that element, and from oxygen, the authors being of opinion that fermentations causing loss of nitrogen cannot proceed in the absence of oxygen.

Each soil was allowed to dry spontaneously, finely ground, and thoroughly mixed; 500 grms. were then put into a flask of 1 or 5 litres capacity, previously filled with carbon dioxide. The soil was agitated in this for some time, a continuous stream of the gas being passed to ensure complete expulsion of air. The flask was then closed with a slightly vaselined stopper and left to itself.

Soil No. 1 was the poorest in nitrogen and also that which was best fitted for the absorption of nitrogen under the favourable circumstances of other experiments; No. 3, on the other hand, showed a tendency to lose rather than gain nitrogen in other experiments. The following table shows the results:—

Soil No.	Nitrogen; Grms. per Kilo.	
	Analysed on May 22nd.	Analysed on October 3rd.
1	0.9740	0.9860
2	1.6551	1.6552
3	1.7440	1.7760

—A. G. B.

XVI.—SUGAR, STARCH, GUM, Etc.

New Methods and Apparatus for the Manufacture of Sugar.

Dingl. Polyt. J. **270**, 173—179.

J. SACHOMEL considers it advisable, after the thick juice has passed through the animal charcoal, used for purifying the former, to follow up with the thin juice and then with water only. By this means a much larger quantity of the substances taken from the thick juice by the charcoal is removed again, than by mere treatment with water. At the same time the charcoal retains considerable quantities of the lime contained in the thin juice. The stronger the syrup passed through the bone charcoal, the more efficient is the latter in keeping back organic impurities, with the exception of colouring-matter; while inorganic substances appear to be more effectually removed when the syrup is weak.

The article concludes with a detailed account of the occurrence and use of strontianite.—A. R.

Raffinose in Beet Sugar.

Deut. Zuckerind. 1888, **13**, 1484.

LIPPMANN'S evidence of the presence of raffinose in the beetroot has been questioned because he extracted it by the strontium process, which is said to produce raffinose by the action of the strontium hydroxide upon other substances in the juice.

From the low diffusion value of raffinose it is probable that it would accumulate in the syrup of the osmosis process; this the author finds to be the case, having extracted the raffinose with methyl alcohol by Scheibler's process; he concludes that raffinose must exist in the beetroot.

The mucic acid and inversion processes for the estimation of raffinose do not give concordant results, the former giving higher values than the latter; thus, in three sugars, obtained by the osmosis process, inversion gave 5.0, 6.3, and 8.4 per cent. of raffinose respectively, while the mucic acid process gave 6.2, 8.0, and 10.3 as the values. This is doubtless due to an accumulation of galactose, or some such substance, convertible into mucic acid.—A. G. B.

XVII.—BREWING, WINES, SPIRITS, Etc.

Progress in Beer Brewing.

C. J. Lintner. *Dingl. Polyt. J.* **270**, 323—331.

This is a resumé of work done in the above-mentioned direction by various authors. P. Lintner considers that experiments by fermentation on a small scale are suitable for distinguishing different kinds of yeast. He found that by fermenting three varieties of yeast under the same conditions, he obtained entirely different results with respect to fermentation, formation of "head," clarification, sediment, and taste. One sample of fermented wort was intensely bitter and astringent, a second, very pure and agreeable, a third, strong but not pleasant to the taste.

The action of "*Denatium pullulans*" in producing ropiness in wort is also discussed. No certainty as to its noxious action can yet be entertained.

Then follows a short description of the sarcina organisms in regard to fermentation. All varieties of these organisms are killed by short exposure to a temperature of 60°.

In an article on "*Saccharomyces apicalatus*," C. Amthor describes its action on maltose. When the maltose is previously boiled with dilute sulphuric acid, this ferment produces in one-third the time about treble the quantity of alcohol that is produced if the treatment with acid be omitted. This appears to prove that maltose is converted into dextrose before being fermented.

The taste of beer after exposure to sun or daylight is the subject of a note by W. Schultze, in which it is stated that Munich and Vienna beer, contained in colourless glass, is very appreciably affected by the direct rays of the sun, as evinced by an unpleasant smell and taste after a few minutes' exposure. The same applies when this class of beer is exposed to diffused sunlight, the only difference being that the change is not so rapid. Pilsener beer is also spoiled by sunlight, but more slowly than the above varieties.

S. Rohm and H. Wichmann, speaking of the Filtration of Beer through the Stockheim filter, which consists of yellow wood-pulp and white cellulose from wood, remark that yeast and other substances causing turbidity are mostly retained, but not bacteria. After having been used, the filtering medium seems to favour the growth of bacteria. Sometimes treble the number of organisms are found in the filtered beer than were originally present.—A. R.

Analyses of Pure Sherry Wines.

E. Borgmann and W. Fresenius. *Zeits. Anal. Chem.* **28**, 71—77.

These analyses were made, primarily, to determine the amount of sulphuric acid contained in pure sherries, which is always high owing to the practice of plastering the grapes during the preparation of the must. Eighteen samples in all were analysed. Nos. 1—12 were of the finest quality, while Nos. 13—18 represent medium and common sorts. The following results were obtained:—

whole of the aldehydes and acetones is distilled off, leaving in the vessel a portion free from these impurities, and which may be subjected to the ordinary processes of distillation or rectification. The distillate containing the impurities is next treated with an excess of a concentrated lye of alkaline bisulphite (30° B \acute{e}), whereby the aldehydes and acetones are converted into aldehyde and acetone sulphites, and the liquid distilled, by which means the alcohol is separated from the impurities. The distillate is redistilled with a base, such as soda, potash, or lime, to free it from any free sulphurous acid that may be present, the resulting distillate being chemically pure alcohol.—J. H.

Improved Means of Oxidising and Decomposing by Electrical Action, Organic Matter and Inorganic Salts in Sewage, Water, and other Liquids. W. Webster, jun., London. Eng. Pat. 1333, January 27, 1887. Amended October 9, 1888. 8d.

In dealing with the treatment of "Sewage and other impure liquids," the use of iron alone, and not of any other materials, is mentioned for the positive electrodes. (See this Journal, 1888, 441.)—E. T.

Improvements in Apparatus for Liquid Purification. W. Oliphant, Jersey City, U.S.A. Eng. Pat. 8627, June 12, 1887. 8d.

The improved form of apparatus is devised with a view to the rapid cleansing of the fouled material used for filtering, and also its rapid removal and renewal. It consists of a closed vessel or tank in which suitable material is disposed and retained in such a manner that the impure water, either with or without a defecating reagent, is successfully passed through beds of material of a finer grade than the one preceding. The impure water on its entrance passes through a coarse bed downwards, rising afterwards through finer media. Each bed is provided with a separate cleansing pipe, and cleansed by hydraulic force, and also a man-hole and cover for the removal of old and the introduction of fresh material.—C. C. H.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A)—CHEMISTRY OF FOOD.

On the Nature of Milk. A. Béchamp. Compt. Rend. 107, 772-775. (Preliminary Extract.)

THREE questions present themselves for solution:—

- (1.) Is milk a mere emulsion of naked fat globules, or is each globule provided with a definite covering?
- (2.) Are other albuminoids besides casein present, and are they different in different kinds of milk?
- (3.) Does milk curdle or ferment without the introduction into it of foreign organisms?

The last two questions are answered by the author in the affirmative, but he reserves the detailed proof for the full memoir.

The first is, however, dealt with as follows:—

Fresh milk or cream is mixed with diluted alcohol, and then filtered. The albuminoids—which are combined with the alkalis—pass into the filtrate, while the fat globules are retained. They are washed with a weak solution of ammonium carbonate in dilute alcohol, which does not attack their enveloping membranes, as is seen when they are examined microscopically. These operations should preferably be conducted at a temperature approaching 0° C. Thus prepared, the fat globules can be preserved almost indefinitely in weak aqueous ammonium carbonate or alcohol. After trituration the fat can be dissolved out by ether (the membranes being left easily distinguishable under the microscope), but brisk churning is necessary to cause the separation of butter if only water be used. When heated, a portion, amounting to at least 1·3 per cent. of the dry globules, remains unfused, retaining the butter fat, however, on account of its spongy structure; from this it can be freed by ether. It appears to be epidermal in character. On ignition the globules leave some ash.—B. B.

(B)—SANITARY CHEMISTRY.

Water for Technical and Drinking Purposes. Gärtner. V. 56f. Ges. 1888, 208.

THE following are some of the conclusions arrived at:—

The water should be free from poisonous substances and pathogenic organisms. There must either be no possibility of the presence of the above, or measures must be taken to remove them. The possibility of infection is much increased by the presence of human dejecta. When such impurity is detected the local conditions should be duly considered in judging the water. To encourage the use of a water its physical properties and the nature and quantities of the dissolved substances should be as similar as possible to those of a water locally esteemed. To form a judgment on one water analogous investigations of several other waters of the same kind, and from the same district, are requisite.

Pouehet lays emphasis on the necessity of using both chemical and bacteriological data in order to form a just opinion of a water.—B. B.

XIX.—PAPER, PASTEBOARD, Etc.

PATENTS.

The Manufacture of an Improved Paper for Use in Copying Letters and the like. A. F. Stoddart, Bristol. Eng. Pat. 4341, March 21, 1888.

THIS invention relates to "the manufacture of an improved material or paper whereby letters can be simultaneously blotted and copied." It consists in treating an absorbent paper with animal, vegetable or mineral oil. The paper is then washed with dilute alkali or water, or is treated mechanically to remove the excess of oil.

In order to obtain a copy of a letter it is simply necessary to press a sheet of the prepared paper on the still wet original, when the latter will be blotted and copied at the same time.—E. J. B.

Treating Vegetable Fibrine in a Manner to Render it more applicable for sundry Useful Purposes. V. Walter, Stuttgart, Germany. Eng. Pat. 13,969, September 28, 1888. 4d.

THE inventor claims the manufacture of a new material made by impregnating cellulose with oils or grease. The material so produced may be used as a substitute for oil-cloth, for socks of boots, and other purposes.—E. J. B.

ERRATUM.

This Journal, December 1888, page 863 and 864, for "Wood Shavings" throughout the abstract, read "Ground Wood Cellulose."

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Use of Mercuric Chloride as a Therapeutic and Prophylactic Agent for Asiatic Cholera. A. Yvert. Compt. Rend. 107, 695.

FORTY-FIVE cases of Asiatic cholera in Tonquin, treated by the author with mercuric chloride, in doses varying from

0.02 — 0.04 grm. per 24 hours, showed a death rate of 20 per cent., whilst the average death rate from the disease in that region was 66 per cent. The author has also tried its use as a prophylactic agent, and in no case did any signs of cholera develop.—C. A. K.

Homo-pteroearpin and Pteroearpin from Red Sandal Wood. P. Cazeneuve and L. Hugoumeq. *Compt. Rend.* 107, 737—740.

THE physical properties of these two substances extracted from red sandal-wood have been previously described by the authors. (This Journal, 1887, 737.)

Homo-pteroearpin, when heated until it decomposes, yields cresol and a little catechol (pyrocatechin). Distilled over zinc dust, a small quantity of a volatile oil, with a comarin-like smell, is formed, together with benzene, toluene, acetylene, ethylene, and carbonic oxide. Hydrochloric acid attacks homo-pteroearpin in the cold, more readily on heating, with the liberation of methyl chloride and the formation of a black resin which dissolves in alkalis to form a fluorescent solution; a small quantity of an amorphous body is held in solution by the hydrochloric acid, which also dissolves in alkalis to form a red fluorescent solution, and is regarded by the authors as probably belonging to the fluorescein group of colours. Hydriodic acid acts similarly to hydrochloric acid. Heated with dilute sulphuric acid (1:10) in a sealed tube, homo-pteroearpin appears to undergo an isomeric change, forming an opaque yellow resin; the sulphuric acid undergoes no change. Fused with caustic potash at 250°—300°, a volatile oil having the smell of comarin results; no fatty or aromatic acid could be isolated. Treated with nitric acid in the cold, a green, amorphous, unstable nitro-derivative is obtained, which is decomposed by boiling water with the formation of resinous bodies. Fuming nitric acid attacks homo-pteroearpin very readily, and a nitro-compound results, which is regarded as trinitro-orcinol, $C_7H_3(NO_2)_3(OH)_2$. It melts at 162°, and yields a characteristic barium salt. Two crystalline bromine derivatives result by treating homo-pteroearpin with bromine, having the formulæ $C_{21}H_{23}BrO_6$ and $C_{21}H_{18}Br_2O_6$; the latter melts at 270°. The composition of these products has led the authors to double the original formula assigned by them to homo-pteroearpin (*v. ante*) viz.:— $C_{12}H_{12}O_3$ to $C_{24}H_{24}O_6$. Neither phenyl hydrazine nor acetic anhydride have any action on the substance; this excludes the presence of an alcohol, aldehyde or ketone group, and the body is regarded as an anhydride of a poly-orcinol, the following constitutional formula being suggested as a probable one:—

Homo-pteroearpin.

Pteroearpin.—The action of the above-mentioned reagents on pteroearpin is similar to their action on homo-pteroearpin, and there is no doubt that the former is a lower homologue of the latter, having the formula $C_{20}H_{16}O_6$. It yields a monobromo-derivative $C_{20}H_{15}BrO_6$.—C. A. K.

On Saccharine. Bruylants. *J. Pharm. Chim.* 1888, 292.

IT is usually supposed that saccharine is completely eliminated with the urine. The author took doses of 0.5, 1, 1.50, and 2 grms. respectively of saccharine, and on examining the urine of 24 hours could only account for 80 per cent., 82 per cent., 84 per cent., and 88 per cent. of the saccharine taken. A ewe received on different days, doses of 1, 2, and 5 grms. of saccharine without suffering in health. The milk at first contained none, the second time traces, and the last time large amounts of saccharine. Saccharine is often

considered an energetic antiseptic, and recommended as an addition to beer. The author finds that 1 per cent. of it does not prevent the alcoholic fermentation, although the process is protracted, whereas an addition of 0.013 per cent. is without any action whatever; 2.5 parts of saccharine per mille cannot prevent the acetification of beer. The pepsin digestion is not disturbed by saccharine, whereas the fermentation of pancreatic fluids, which contain 1 per cent. of it, proceeds very slowly. The author also confirms the fact that taken as a medicine it is harmless. For some considerable time he took daily doses of 3 grms. without the least injurious effect; it did not even interfere with the digestion. (Compare this Journal 1888, 688.)—S. H.

The Relations between Atropine and Hyoseyamine. A. Landenburg. *Ber.* 21, 3065—3070.

WILL (this Journal, 1888, 584) found that hyoseyamine is converted into atropine when treated with dilute alkalis or when heated above its melting point. Will and Bredig, who investigated this subject more fully, came to the conclusion that atropine is an optically active base ($\alpha_D = -1.89$).

The author prepared atropine aurochloride from a sample of the purest commercial atropine (which was further purified by several recrystallisations), and recrystallised it 14 times; the resulting salt melted at about 140°, and an 18 per cent. solution of the atropine obtained from this salt was optically inactive.

When an 8 per cent. alcoholic solution of commercial atropine is mixed with a few drops of very dilute soda, and kept for two hours, the solution is still optically active, but if the base obtained from the solution be recrystallised several times, its rotatory power decreases. When a 6 per cent. alcoholic solution of atropine is mixed with a small quantity of soda, and kept for 5 hours, the solution is optically active; after standing for 19 hours longer the solution is still optically active, but if the base be then twice recrystallised from dilute alcohol, the pure compound obtained has no rotatory power.

From these results the author concludes that atropine is an optically inactive base, standing in the same relation to hyoseyamine as racemic acid to levotartaric acid, and that the conversion of hyoseyamine into atropine, although possible, has not yet been accomplished. He also found that when atropine aurochloride, prepared from ordinary atropine, is recrystallised many times, small quantities of the hyoseyamine salt are obtained, and he is also of the opinion that the supposed coconversion of hyoseyamine into atropine results from the employment of impure materials.

—F. S. K.

Narcotine. W. Roser. *Ann.* 249, 156—172.

A CONTINUATION of researches on the derivatives of narcotine. (This Journal, 1888, 518.) The present paper deals with those derivatives which have cotarnine for their starting point, and the author prefers Anderson's method, for the preparation of this substance from narcotine, by the action of nitric acid in preference to manganese dioxide and sulphuric acid. The melting point of cotarnine is given as 132°—133°, at which it also begins to decompose. By the action of methyl iodide on cotarnine a product is obtained containing the two following substances:—

Cotarnine hydriodide, $C_{12}H_{13}NO_3HI$, forms glittering yellow needles sparingly soluble in water and cold alcohol.

Cotarninemethylhydriodide, $C_{14}H_{20}NO_3I$, is easily soluble in hot water, and crystallises by slow cooling in long glittering needles of light yellow colour. On digesting this with silver chloride the corresponding chloride, $C_{14}H_{20}NO_3Cl \cdot 3H_2O$, is obtained, and is distinguished by its readiness to form large clear crystals. Cotarninemethylhydriodide is remarkable in being derived from cotarnine, not merely by the addition of methyl iodide but by the inclusion of a second methyl-group. On treating the aqueous solution with caustic soda, a separation of oily drops ensues accompanied by the smell of a volatile base. The decomposition of the base of the salt is expressed by the equation—

The oily body forms on cooling a white crystalline compound, $\text{C}_{11}\text{H}_{19}\text{O}_4$, which, having the characters of a ketone, is termed *cotarnone*. The volatile base is trimethylamine. From the nature of this change the constitutional formula of cotarnmethinmethyliodide must be $(\text{C}_{11}\text{H}_{11}\text{O}_4)\text{N}(\text{CH}_3)_3\text{I}$, and from a consideration of the transformation undergone by cotarnine in these reactions, the author draws the following conclusions:—

"The formula of cotarnine is not $\text{C}_{12}\text{H}_{13}\text{NO}_3 \cdot \text{H}_2\text{O}$, but $\text{C}_{12}\text{H}_{13}\text{NO}_3$, the so-called water of crystallisation belonging to the constitution. Cotarnine is a secondary base.

"A pyridine group is not contained in free cotarnine, but is contained in its salts."

Cotarnone, $\text{C}_{11}\text{H}_{19}\text{O}_4$, is easily soluble in alcohol, ether or acetic acid, and crystallises from alcohol in rhombic plates, melting at 78° . It is an indifferent body, stable against alkalis, but transformed on warming with acids into dark-coloured products.

Cotarnonoxime, $\text{C}_{10}\text{H}_{11}\text{O}_3(\text{NOH})$, is formed on warming cotarnone with hydroxylamine hydrochloride in alcoholic solution. It crystallises from dilute alcohol in fine needles, melting and decomposing at 130° – 132° .

Cotarnic acid, $\text{C}_8\text{H}_6\text{O}_3(\text{COOH})_2$, is obtained from cotarnone by the action of potassium permanganate. It crystallises readily from water, and melts at 178° with decomposition. It forms an acid potassium salt, which, on double decomposition with silver nitrate, yields a neutral silver salt and free acid. The author observes that hydrastinine comport itself on treatment with methyliodide in a manner strictly analogous to cotarnine, yielding a volatile base, and an indifferent substance as final products.

The formula for cotarnine, and its relation to hydrocotarnine, as deduced from the results of these researches, may be thus expressed.

Cotarnine—

Hydrocotarnine—

XXII.—EXPLOSIVES, MATCHES, Etc.

Improvements in the Explosives Industry. O. Guttman.
Dingl. Polyt. J. **270**, 215–223.

H. GÜTLER (German Pat. 44,078, December 19, 1887) has patented further improvements in his charcoal furnace. The wood is introduced into the furnace in the form of pulp. The improved apparatus cannot be described in the absence of drawings; but it appears to be an important addition to this special branch of powder manufacturing.

Le Boulenger's well known chronograph has been adapted to meet the requirements of the present high velocity of projectiles. The chief alteration consists in placing the wire frames that are shot through 100 metres apart, instead of, as formerly, 50; and in the same proportion the time recorded is increased. A special arrangement allows of the apparatus being used in places where the range is less than 100 metres.

The *French Explosives Commission* has examined the conditions which give rise to the ignition of fire-damp by certain explosives.

According to a report of Mallard and Le Chatelier (*Revue Industrielle*, 1888, 298), the heat generated by an explosion must exceed $2,200^\circ$ before it will ignite fire-damp. Equal parts of dynamite and soda crystals, or sulphate of soda containing 10 aq., or ammonia alum, or ammonium

chloride, when detonated in an atmosphere of fire-damp, failed to ignite it even in the presence of coal dust.

Mixtures of nitro-glycerol and gun-cotton with nitrate of ammonium have a special advantage because the nitrate acts as an explosive, but depresses the temperature; the temperature of the explosion being, in the case of nitrate of ammonia $1,130^\circ$, that of dynamite, nitro-glycerol, and gun-cotton, being $2,940^\circ$, $3,170^\circ$, $2,636^\circ$, respectively. The Commission found that 20 parts of dynamite or nitro-glycerol with 80 parts or more of nitrate of ammonium failed to ignite the most inflammable fire-damp.

A. Zettler has introduced a new electro-magnetic exploder. According to experiments by Prof. Carl, it is capable of exploding 80 detonators at one time and weighs only 14 lbs.

A new method for determining the percentage of glycerol in the crude material is suggested by R. Benedikt and M. Cantor. It is based on the observation that glycerol is converted into triacetin on boiling with anhydrous acetic acid. The triacetin is determined by dissolving in water, neutralising with soda solution and titrating back the excess.

The increased demand for quality and purity of explosives has brought about a change in the methods of manufacture of the same, and on sounder and more scientific principles. Greater attention has of late been directed to electrical phenomena so often observed during the process of manufacturing gunpowder, but concerning which no safe conclusions have been arrived at owing to the absence of the evidence of reliable observers.

The most important and also the most common occurrence is the accumulation or attraction of atmospheric electricity during storms. The buildings of explosive works, as a rule, are detached, and often in elevated positions. In England it is prescribed that the lightning conductor should be fixed *on to the building itself*. In other countries it is considered sufficient to attach the lightning conductor to a high staff near to the building, and we are of opinion that the buildings in question are afforded more protection. In many cases the lightning conductor has been known to favour the discharge of electricity, and it is suggested that an explosion of a powder magazine at Salonica occurred in this way.

As regards the machinery in the buildings, precautions should be observed against the accumulation of atmospheric electricity as well as from other sources, more especially in the manufacture of explosives, of which sulphur is a constituent. In the powder works of W. Güttler the sulphur mills are connected with the earth so as to carry off the electricity, and since this arrangement has been introduced the sulphur has never fired, it being, previously, a matter of constant occurrence.

In another large powder works in Germany, not long since, an explosion occurred in the press-house after a storm. The powder was between chlorite plates, and under pressure before the commencement of the storm. When the storm had ceased, a workman released the pressure and proceeded to separate the cakes from each other. According to a statement made by him before his death, a spark 19 centimetres in length was discharged into his finger as he was in the act of lifting one of the cakes.

W. T. Reid has observed that warm air passing over nitro-cellulose generates electricity in considerable quantities.

The generation of electricity has been observed in other industries during manufacturing processes, and several instances are quoted; but, according to the author, no instance has come to his knowledge which is of importance or which has caused immediate danger.

The author considers that the extensive application of rubber, ebonite, &c. to machinery used for the manufacture of explosives is somewhat hazardous. In England, for instance, the shoots of the separators and the bed-plates of the granulating mills are lined with rubber composition. This stuff has the advantage that it wears well, and possesses certain elasticity combined with great strength, &c., but under favourable conditions such a bed-plate might act as an electrophorus.

The author considers the question of the accumulation and attraction of electricity one which should receive greater

attention, and observes that it should be made compulsory to connect all machinery and apparatus with the earth by conductors properly constructed.—C. N. II.

PATENTS.

Improvements in Explosive Compounds. H. E. Newton, London. From A. Nobel, Paris, France. Eng. Pat. 4179, December 2, 1875. (Third Edition.) 6d.

THE object of this invention is to convert at the ordinary temperature, liquid explosive substances, such as nitroglycerol, the nitrates of methyl, ethyl and amyl, and nitrobenzene into a viscid or pasty state by incorporating these with another substance capable of gelatinising or thickening them, such substances being chosen which detract little or nothing from their explosive force, such as, for instance, gum-cotton.

"Nitroglycerin may be gelatinised by dissolving in it nitrated cellulose, known as collodion cotton."

About 7 per cent. of gum-cotton is found to be sufficient to form a solid jelly, "which is very safe and highly suitable for every purpose to which very powerful explosives can be applied."

The addition of nitrobenzene, dinitrobenzene, charcoal, or ordinary gunpowder to gelatinised nitroglycerol is proposed, with a view of modifying the rapidity of combustion, and also of lowering the freezing point of the nitroglycerol.—C. N. II.

Improvements in the Manufacture of Charcoal. O. Bowen, A. S. Tomkins, and J. Cobeldick, London. Eng. Pat. 11,537, August 24, 1887. 4d.

THE object of this invention is to produce a charcoal rich in hydrogen, and suitable for the manufacture of gunpowder. For this purpose wood or suitable carbonaceous matter is subjected to a heated current of air mixed with hydrogen. The furnace employed has been described in Eng. Pat. 509 of 1881 and 1457 of 1886.—C. N. II.

Improvements in Machines for the Compression of Gunpowder, and for similar Purposes. A. Greenwood, Leeds. Eng. Pat. 1153, January 25, 1888. 11d.

THE object of this invention is to provide for the manufacture of small cylindrical or conical pellets, for use in rifle cartridges, or of prismatic or cubical powder.

The machine works automatically and is designed to perform the following operations:—

To measure the quantity of powder required for each pellet; to place this powder in a mould; to insert one or more needles into the mould and apply vertical and lateral pressure, finally withdrawing the needles, and after removal of the pressure ejecting the finished pellet. For details the specification and drawings must be consulted.—C. N. II.

Improvements in Explosive Compounds. C. D. Abel, London. From H. Schöneweg, Dudweiler, Germany. Eng. Pat. 1591, February 2, 1888. 4d.

AN explosive mixture consisting of 20 parts of dinitrobenzene, 80 parts of potassium nitrate, and a proportion of ammonium oxalate, varying between 5 per cent. and 12 per cent. of the other two ingredients combined.

The oxalate of ammonia is added with a view of producing a flameless explosive.—C. N. II.

Improvements in the Manufacture of Explosives. E. Turpin, Colombes, France. Eng. Pat. 4310, March 20, 1888. 6d.

THIS invention relates to an improved smokeless powder for firearms, which is prepared by dissolving gun-cotton more or less nitrated in any solvent most suited to the kind of gun-cotton employed, e.g., "nitrobenzene and other nitro-bodies of the aromatic series, aniline, aldehydes, amido-compounds of various kinds, acetone, sulphuric, nitric, acetic, and other ethers." Also "ammonia in solution in sulphuric or other ether, acetone in solution in sulphuric or other ethers or mixtures of ethers are suitable for dissolving gun-cotton more or less nitrated."

The resulting paste is spread upon plates or trays with raised edges and allowed to dry. When sufficiently dry the sheets are rolled out to the desired thickness, and subsequently cut crosswise by suitable machinery in order to form small cubes. The rapidity of combustion of the powder is retarded by the addition of camphor, nitrobenzene, nitrotoluene, paraffin, &c. By varying the proportions of the ingredients above-named, "powders may be obtained adapted to suit all requirements."—C. N. II.

Improvements in the Method of Preparing High Explosives for Use and in the Charges of Cartridges made of such Explosives. J. W. Graydon, Washington, U.S.A. Eng. Pat. 6498A, May 1, 1888. 8d.

THE object of this invention is to prevent exudation or other physical change in high explosives, "as, for instance, dynamite, melinite, and roborite." The invention is carried out by separating the mass of explosive into a number of small portions, and entirely enclosing each portion in a separate envelope so as to form explosive pellets which can be packed together in a suitable wrapper or case to make a cartridge, or to be used or handled loosely without any casing.

The purpose of the invention can also be attained by loading the explosives into cartridges containing partitions which separate it into small portions. Drawings of cartridges are attached to the specification.—C. N. II.

XXIII.—ANALYTICAL CHEMISTRY.

A New Spirit Lamp for obtaining High Temperatures, a Substitute for the ordinary Gas Blow Pipe. R. Rosenlecher. Chem. Zeit. 12, 1622—1623.

THE shape of the lamp is that of the common Bunsen lamp, but, instead of a single wick, there are two concentric circular wicks *a* and *b* (Fig. 1). The space between the two

Fig. 1.

wicks is formed by platinum foil into a channel *c*, for the admission of air under pressure, which channel is provided at the top with 10 small holes, bored aslant at an angle *a*¹, so as to concentrate the heat on one point. The amount of air required is very small, and can be easily supplied by a hand or foot blower of medium size. If the crucible to be heated be introduced into a fire-clay furnace (Fig. 2), a

Fig. 2.

white heat is readily attained, and if the fire-gases which escape be not likely to reduce the contents of the crucible, the furnace may be covered with a lid *d*, whereby the gases escape in the direction indicated by the arrows. It will be found best to have the height of wick from 2 to 3 mm., and the height of the flame from 4 to 5 cm. The burner may also be used in connexion with the common Berzelius lamp by being screwed down into the alcohol receiver of the lamp.—S. H.

An Apparatus for the Electrolytic Estimation of Metals. C. Levoir. Zeits. Anal. Chem. **28**, 63.

THE solution to be electrolysed is contained in a platinum dish supported on three metallic knobs, which serve to conduct the current from the positive pole of the battery. A smaller platinum dish is suspended inside the first dish by means of three platinum wires, the distance between the two basins being three centimetres. The three wires are attached to a stouter platinum wire, which dips into a mercury cup connected with the negative pole of the battery. The liquid to be electrolysed is thus situated between the parallel surfaces of the two dishes. During the passage of the current, the oxygen, liberated on the bottom of the upper dish, bubbles through the solution, and keeps it in constant circulation. Every portion of the solution is, therefore, brought into contact with the negative electrode, resulting in the rapid and complete deposition of the dissolved metal.—H. T. P.

Estimation of Zinc in Presence of Manganese. G. Neumann. Zeits. Anal. Chem. **28**, 57—58.

THE author finds that Bragard's method for the separation of zinc from formic acid solution as sulphide in presence of iron and nickel, is also applicable to the estimation of zinc in presence of manganese. The ratio of zinc to manganese, in the mixtures analysed, varied between wide limits. The results obtained were very satisfactory.

—H. T. P.

Arsenic in Precipitated Calcium Phosphate and its Estimation. H. Fresenius. Zeits. Anal. Chem. **28**, 64—67.

IT is well-known that precipitated calcium phosphate has been used for some time with considerable success as an addition to cattle food. The arsenic generally contained in the hydrochloric acid employed in the manufacture of the phosphate, finds its way into the latter in the shape of

calcium arsenite and arsenate, and if present in quantity might exert an injurious influence on the health of the cattle fed with the phosphate. For the estimation of the arsenic the author recommends the method and apparatus devised by R. Fresenius and E. Hintz. Ten grms. of substance are placed in a retort and covered with 100 cc. of HCl of 1.19 specific gravity. When the precipitate has mostly dissolved, 5 cc. of a cold saturated solution of ferrous chloride are added, and the whole nearly distilled to dryness. The arsenic is then estimated in the distillate as trisulphide in the usual manner. Twenty-five samples examined by this method were found to contain percentages of arsenic (metal) varying from 0.028 to 0.17.

The question as to the maximum quantity of arsenic permissible in phosphates used for feeding purposes, in the opinion of the author, can only be solved by a series of practical feeding trials made with phosphates containing gradually increasing percentages of arsenic.—H. T. P.

The Estimation of Copper Electrolytically. F. Rüdorff. Ber. **21**, 3050.

IN estimating copper electrolytically, it is advantageous to acidify the solution with nitric acid; but when chlorides are present, considerable time is taken up in evaporating the solution with sulphuric acid.

The author found that when an ammoniacal copper solution is electrolysed, the metal separates in a spongy condition, but that if 2 to 3 grms. of ammonia or potassium nitrate be added, and then about 10 cc. of ammonia for every 100 cc. of the solution containing 0.1—0.3 gm. of metal, the latter separates in excellent condition, even when the strength of current employed varies between considerable limits. The operation is at an end when the solution has become colourless.—F. S. K.

Determination and Separation of Zinc. J. Riban. Bull. Soc. Chim. **50**, 518—520.

See this Journal, 1888, 771.—C. A. K.

Separation of Cobalt and Nickel by the Nitrite Method. M. Baubigny. Compt. Rend. **107**, 685—686.

THE author points out that lead forms a triple nitrite with potassium and nickel, similar to those obtained with the alkaline earths. It is a yellow-orange coloured precipitate, which is only slightly soluble in water, even when acidulated by acetic acid. The exact composition of the compound has not yet been determined, but it is clear that the presence of lead, like that of the alkaline earths, must interfere with the separation of cobalt and nickel by the nitrite method.—C. A. K.

Tin. L. Vignon. Compt. Rend. **107**, 734—737.

IF metallic zinc be employed to precipitate tin from a solution of stannous or stannic chloride, the precipitated metal possesses the ordinary properties of tin, provided the solution contains an excess of acid; but if there be no free acid in the solution, i.e., if it be pure stannous or stannic chloride, the deposited tin always contains some stannous oxide. The quantity of the oxide formed increases with the length of time during which the deposition has taken place. The presence of this stannous oxide (SnO), which in the samples of deposited tin examined varied from 22 per cent. to 33 per cent., renders the metal quite infusible, and causes it to burn away, when heated in the air, without melting. When heated to a red heat in a current of carbon dioxide the tin sublimes in the form of minute globules, whilst a greyish powder is also deposited consisting mainly of stannous oxide. The specific gravity of this partially oxidised metal was found to be 6.910 to 7.198 at 15°; examined under the microscope it appeared of a fine dendritic structure, differing in this from pure tin, which, when precipitated on zinc, consists of compact needle-shaped crystals.—C. A. K.

On the Analysis of Commercial Scheelite. K. Rusag
Chem. Zeit. 12, 1316.

AUSTRALIAN scheelite, commercially known as the crude material from which tungsten and tungstates are manufactured, contains as impurities, quartz, calcium carbonate, silicates, sulphur ore, and arsenical ores. If metallic iron occurs, showing its presence by magnetic attraction, it may be supposed to owe its origin to instruments used in mining operations.

It is a moot point whether, in testing the commercial product, it is preferable to commence with the decomposition of the tungstate of lime by means of acids, or with breaking it up by fusion with carbonate of soda. If the latter process be adopted, the presence of silica in the fused product necessitates recourse to a variety of difficult operations, and the possible formation of silicate of tungsten may necessitate further roundabout processes. It is not possible to decompose the tungstate of calcium by means of solutions of alkaline carbonates and oxalates, nor did the author succeed by means of boiling nitric acid in rendering the whole of the tungstate accessible to the subsequent action of ammonia. A better result is obtained with concentrated sulphuric and hydrochloric acids, which both decompose it completely when heated for a sufficiently long time, the residue, exhausted by water and ammonia, generally proving free from tungstates when fused with soda. Hydrochloric acid is the more easily applied of the two. It does, it is true, dissolve a portion of the tungstate, but precipitates it again when diluted.

But as it is necessary, even when employing hydrochloric acid, to submit the silicates which have been separated to further tests, the most practical method appears to be to first remove the silica as fluoride of silica, which may be done without loss of tungstate by a mixture of hydrochloric acid and hydrofluoric acid; while, on the other hand, by heating with fluoride of ammonia, the formation of volatile combinations of fluorine and tungsten (also observed by Marignac) could not be avoided.

According to this method, from 2 to 3 grms. of finely-powdered scheelite are heated with hydrochloric and hydrofluoric acids until the silicic acid and the excess of hydrofluoric acid have entirely evaporated. The dry residue is again moistened with fuming hydrochloric acid, diluted after some time with an abundance of hot water, heated to boiling point, and left to settle.

The tungstic acid which has separated is washed without bringing it on the filter by decanting with hot dilute hydrochloric acid, dissolved in ammonia, and filtered after rendering it capable of filtration by heating and the addition of sal-ammoniac. The filtrate is evaporated to dryness in a large flat porcelain dish. The residue of tungstate of ammonia, if pure, would firmly adhere to the dish, but this is prevented if, during filtration or afterwards, sufficient sal-ammoniac has been added, and particularly if it has been heated until the point when decomposition sets in. The salt is now transferred to a large tared porcelain crucible, any residue which adheres to the dish being dissolved in ammonia, sublimed sal-ammoniac (free from ash) added, and evaporated as before. This is added to that in the crucible, and the operation repeated, if necessary, once or twice. The sal-ammoniac is driven off, and the tungstate of ammonia decomposed at a temperature far below the visible red heat, which is only brought to bright red at the end of the operation.

The remaining tungstic acid is of a pure yellow colour, provided the use of platinum vessels for ignition be avoided. Although only very sparingly soluble in ammonia, fused with soda it dissolves in water without leaving a residue, and, when boiled with sal-ammoniac, does not precipitate flocks of silicic acid or alumina.—T.

The Detection of Acetanilide. Zeits. Anal. Chem. 28,
103—104.

VARIOUS reactions are given for the detection of this substance, which is used medicinally to a considerable extent under the name of "antifebrin." G. Vulpius recommends the following test. A few centigrammes of the substance are boiled with 1 cc. of potash solution for a short time. A glass rod dipped in a bleaching-powder solution is then

suspended over the liquid; the bleaching-powder solution quickly assumes an amber-yellow colour, especially when viewed by transmitted light. By reflected light it has a violet tinge, and after long boiling, a distinct violet colour is produced. Aniline treated in a similar manner gives an immediate violet colouration, but no intermediate yellow tinge is produced. To detect acetanilide in urine, Vulpius gives the following:—The concentrated urine is boiled for a few minutes with HCl, cooled, extracted with ether, the ether evaporated, and the residue dissolved in water and mixed with a few cubic centimetres of an aqueous solution of phenol, and half its volume of a 1 per cent. solution of bleaching-powder. A brownish-red colouration is produced, which is changed to a beautiful blue by ammonia.

Vyon heats acetanilide gently with mercurous nitrate, whereby a body is produced which dissolves with a green colour in alcohol.

D. Cella and Arzeno heat a few centigrammes of the substance very gently with 2—3 drops of a solution of mercurous nitrate, and after solution has been effected, add 2—3 drops of strong sulphuric acid, when a blood-red colouration is produced. The last reaction is given by resorcinol, phenol, salicylic acid, tannic acid, gallic acid, and thymol, but not by benzoic acid.

F. A. Plückiger rubs up two parts of acetanilide with one part of caustic potash, moistened with chloroform, transfers the mixture at once to a test-tube, and heats very gently. The mixture turns brown, and gives off the very characteristic smell of phenyl carbaniline.—H. T. P.

Detection of Cotton-Seed Oil in Lard. Bishop and L. Engé.
J. Pharm. Chim. 1888, 348.

AMERICAN lard frequently contains as much as 50—60 per cent. of foreign fats, such as olein, "oleomargarin," cotton-seed oil, and cotton-seed stearin, while hard tallow is added to give the product the requisite consistency.

The best means of detecting cotton-seed oil is by the use of Bechi's test, of Labiche's reaction with lead acetate and ammonia, and of the rise of temperature with sulphuric acid. These are executed by the authors as follows:—

(1.) Bechi's test:—5 grms. of the clear melted fat are heated with 20 cc. of absolute alcohol and 3 cc. of an alcoholic solution of silver nitrate, containing 2 grms. in 250 cc., for 10 minutes on the water-bath, with continuous shaking. In the presence of cotton-seed oil a colouration appears, which may also be observed in the fat itself on solidifying, and—if the alcohol be decanted off and the cake of fat dissolved in ether or petroleum spirit—in its cold solution.

(2.) Labiche's test:—25 cc. of a solution of lead acetate containing 500 grms. per litre (heated to about 35° C.) are mixed with 25 grms. of the clear melted fat, and 5 cc. of ammonia (22° B. or sp. gr. '924) added with vigorous stirring for some minutes. The colour (orange-red) is observed after 24 hours.

(3.) Rise of temperature with sulphuric acid:—20 grms. of the clear fat are allowed to cool to about 30° C., the temperature exactly taken, and 20 grms. of sulphuric acid of a specific gravity not less than 1.836 run in, while the mixture is stirred vigorously with a thermometer; when the temperature ceases to rise, it is read off, and the total rise in temperature thus ascertained. Treated thus, genuine lard gave a rise of temperature of 35° C., with an acid of specific gravity of 1.837; and of 42° C. with one of specific gravity 1.842, while with the former acid a very old sample of cotton-seed oil gave 70° C., and a new one 66° C.

In all three tests the age of the sample does not much affect their value, though with Bechi's test a greater reduction of silver nitrate takes place with a new than with an old oil, and with Labiche's reaction the colouration is more marked in the case of an old oil.

The authors conclude that the detection of cotton-seed oil in lard is easy, but that no reliable method exists for its estimation.

(For recent papers on the same subject, see the "Analyst," 13, 161, 165, 168, 170, 172, 189, 203.)—B. B.

Detection of Adulterations in Vegetable Fatty Oils.

W. Peters. Arch. Pharm. 1888, 322.

The following points are to be observed :—

1. The melting point of the mixture of insoluble fatty acids obtained by saponification with hydrochloric acid or dilute sulphuric acid. In pure olive oil this should be between 24° and 29°; if above 29°, cotton-seed oil is present; if below 24°, linseed, poppy, or castor oil is present.

2. The colour imparted to a solution of the oil in nitric acid and sulphuric acids by the addition of sugar dissolved in hydrochloric or nitric acid. This will detect sesamé oil in olive and almond oils. Cotton-seed oil is coloured by the addition of nitric acid or a strong solution of antimony chloride. Rape oil will reduce alcoholic silver nitrate; earth-nut oil gives no colour reaction with acids.

3. The colours developed by the elaidin reaction. Cotton seed, sesamé, and peach-kernel oils are thus detected in olive oil.

4. The different solubilities of the fatty acids in 90 per cent. alcohol. Such a solution of the fatty acids from cotton-seed or earth-nut oil solidifies at 15°; so that if these oils be present in olive or almond oil, the alcoholic solution of the fatty acids will become turbid at 15°.

5. Hübl's iodine absorption value for pure olive oil is 80·2–85; a higher number indicates adulteration.

—A. G. B.

A Source of Error in the Determination of Benzene in Gas Mixtures. E. P. Treadwell and H. N. Stokes. Ber. 21, 3131–3133.

BERTHELOT published in 1876 (Compt. Rend. 83, 1255), a method for the analysis of illuminating gas, which consisted in absorbing carbonic acid by potassium hydrate, the "heavy hydrocarbons" by bromine water, benzene by fuming nitric acid, oxygen by an alkaline solution of pyrogallol acid or by phosphorus, and carbonic oxide by cuprous chloride. C. Winkler recommended this method in his "Handbook of Technical Gas Analysis." The authors found very variable figures in using red nitric acid, according as the gas was shaken with the acid a short or a long time. An illuminating gas contained 12 per cent. of carbonic oxide as tested by ammoniacal cuprous chloride; and when 100 cc. of the same gas, freed

from carbonic acid and heavy hydrocarbons, were shaken with red nitric acid, the figures obtained were as follows :—

Volume of the Gas free from CO ₂ and C ₂ H ₂ .	The Time of shaking with Red Nitric Acid.	Volume of the Gas after the Absorption.	
cc. 97·3	Minutes. 5	cc. 87·7	Per Cent. 3·6
..	10	86·0	5·3
..	15	83·6	7·7
..	20	82·2	9·1
..	25	81·2	10·1

In order to discover what constituent of the gas was absorbed by the nitric acid, the behaviour of this acid to carbonic oxide was investigated, when it was found that nitric acid absorbed carbonic oxide quantitatively. From this it was to be expected that nitric acid should absorb carbonic acid, and direct experiments proved this to be the case. It is, therefore, obvious that red nitric acid must not be used for the determination of benzene in gas mixtures containing oxides of carbon. As to the use of bromine-water for the absorption of gases of the ethylene series, very great care should be observed. It was found that bromine-water absorbed not only these gases, but also benzene. Bromine-water is therefore altogether unsuitable for the separation of the "heavy hydrocarbons" from benzene. There exists no process at present that allows of a separate determination of benzene and the gases of the ethylene series, and analysts must be satisfied to simply state the total sum of heavy hydrocarbons in their gas analyses.—S. II.

Estimation of Ash in Coke. F. Stolba. Listy Chem. 12, 63.

ONE grm. of the finely-powdered sample is mixed with 1 grm. of precipitated silver and ignited in a platinum dish at a red heat; incineration proceeds much more quickly than in the absence of the silver.—B. B.

The Examination of Spirit. H. Bornträger. Zeits. Anal. Chem. 28, 60–62.

THE principal impurities found in commercial spirit are aldehyde, acetal, and amyl alcohol. In the pure state, or when present to a considerable extent in spirit, these bodies give the following reactions :—

	Aldehyde.	Acetal.	Amyl Alcohol.
1. Boiling point of the chemically pure bodies	21° C.	104° C.	130° C.
2. Specific gravity	0·807	0·821	0·825
3. Behaviour with water	Easily soluble.	Insoluble.	Insoluble.
4. Behaviour with chloroform	Is taken up, the chloroform increases in volume and sinks to the bottom. A silver mirror is formed.	Same as for aldehyde.	Same as for aldehyde.
5. Behaviour on warming with an ammoniacal silver solution and water.		No mirror, but traces of reduction.	No action.
6. Behaviour with a colourless solution of magenta and sodium hydrogen sulphite in water.	Strong violet colouration, which is turned blue by strong HCl (1 in 500,000 may be thus detected).	No colouration.	No colouration.
7. Behaviour with an equal bulk of strong sulphuric acid.	Strong brown colouration.	Same as for aldehyde.	Same as for aldehyde.
8. Behaviour with an equal bulk of caustic potash solution (1–3).	Yellow colouration.	Same as for aldehyde.	Same as for aldehyde.
9. Behaviour with an equal bulk of strong sulphuric acid, strong potash solution being subsequently added.	Considerable separation of carbon, with slight smell of acrolein (acrylic aldehyde).	Strong smell of acrolein.	Colourless fluid of agreeable odour.
10. Behaviour with three drops of strong HCl and 10 drops of colourless aniline oil.	Yellowish-red colouration (in presence of much aldehyde).	No colouration.	Beautiful raspberry colouration (in presence of 0·05 per cent.).
11. Behaviour on dilution with two parts of water, extraction with chloroform, separation, and addition of three drops concentrated HCl and 10 drops of colourless aniline oil to the extract.	The chloroform is coloured yellowish-red (no reaction with traces).	No colouration.	The chloroform is coloured deep red in presence of large quantities; small amounts give a pink colouration.
12. Behaviour with a strong solution of potassium iodide.	Strong browning.	No colouration.	No colouration.

The colour tests are best performed in small porcelain dishes.

A commercial spirit is tested for the above constituents most conveniently as follows:—

I. (1.) A sample is largely diluted with water. If oily drops collect on the surface, they must be tested for acetal, by treating with strong sulphuric acid and potash (test, No. 9), and for amyl alcohol according to test No. 10.

(2.) Another portion is examined for aldehyde by means of tests 6 and 12.

II. If no separation of oily drops take place, the spirit is examined as follows:—

(1.) For aldehyde as in I. (2).

(2.) Another portion is diluted with two parts of water, and shaken out with chloroform. The chloroform extract is evaporated at a low temperature, and the residue tested for acetal and amyl alcohol as in I. (1).—H. T. P.

The Estimation of Phosphoric Acid in Sweet Wines, and its Bearing on the Purity of the Wine. W. Fresenius. *Zeits. Anal. Chem.* 28, 67—71.

The author finds that in the determination of phosphoric acid in sweet wines, the results are liable to be low, owing to the volatilisation of phosphorus during ignition of the extract to ash, caused by the action of carbon on phosphates. The following numbers were obtained, on the analysis of Tokay and Malaga wine, by different methods:—

P₂O₅ per Cent.

Tokay. Malaga.

1. Direct estimation in ash.....	0.0336	0.0256
Repetition.....	0.0368	..
2. After removal of the spirit the residue was suitably diluted, fermented with 3 cc. of yeast, dried, ignited (yeast and all), and the P ₂ O ₅ determined, allowance being made for P ₂ O ₅ in yeast.....	0.0339	0.0256
Repetition.....	0.0412	..
3. Same as above (2), only a very few yeast cells being added.....	0.0431	0.0257
4. The wine was evaporated with the addition of 6 grams of sodium carbonate and a little potassium nitrate, and the dried residue gradually added to fused potassium nitrate. The P ₂ O ₅ was determined in the solution of the melt.....	0.0427	0.0263

According to the standards imposed by List, a sweet wine (whether prepared from dried grapes or concentrated must) containing 20 per cent. of sugar ought to contain at least 4 per cent. of non-sugar extract and 0.04 per cent. of phosphoric acid. Wines which do not answer to these conditions are considered to have been adulterated, most probably in the first place with cane sugar. The author points out that non-concentrated sweet wines can be prepared in another way, namely, by adding to the must, when only very partially fermented, enough alcohol to stop the fermentation. To decide whether a wine has been prepared in the manner described, or whether cane sugar has been added, a determination of glycerol must be made. The following examples are given:—

	Tokay.	Cape Wine.	Muscatel.
Specific gravity.....	1.0729	1.0543	1.0653
Polarisation:—			
Direct.....	11	- 6.5	- 7
After inversion.....	11	- 6.5	- 7
After fermentation.....	± 0	± 0	± 0

Tokay. Cape Wine. Muscatel.

100 cc. of the wine contain:—

	Grams.	Grams.	Grams.
Alcohol.....	10.16	13.65	12.31
Extract.....	22.40	19.84	22.55
Ash.....	0.26	0.20	0.26
Free acid.....	0.50	0.35	0.34
Glycerol.....	0.89	0.13	0.15
Phosphoric acid.....	0.0292	0.0204	0.0190
Sugar, calculated as glucose.....	19.66	17.51	20.80

As the glycerol in a pure wine amounts to less than $\frac{1}{10}$ th or even $\frac{1}{100}$ th of the alcohol present, it will be seen from the above numbers that the Tokay wine has been sophisticated with cane or other sugar. The other two examples may be looked upon as musts in which the fermentation has been stopped by the addition of alcohol.

—H. T. P.

ERRATUM.

The following articles are free of duty:—Acids, carbonic, citric, muriatic, sulphuric; alum; antimony, in ingots; arsenic, crude; bluestone; carbolic powder; chloralium; coppers; dye-woods and dye-stuffs for manufacturing purposes only; ink, printing; creosote, crude; lime, carbolate of; lime, chloride of; logwood; manures; Muntz metal; myrobolans; paraffin and mineral wax; phosphorus; pitch; potash and pearlash; pottery materials, viz., litharge, china clay, Cornish stone, felspar, manganese, and oxide of cobalt; resin; salt, rock; shellac; soda ash; caustic soda; silicate of soda; solder and soldering fluid; stearine; sulphate of magnesia; sulphate of copper; sumac; tannin; and tannin extracts; tar; terra japonica; valonia; and vegetable black.

MISCELLANEOUS TRADE NOTICES.

THE PROPERTIES OF SACCHARIN.

With reference to the notification published on page 419 of the October (1888) number of the *Board of Trade Journal*, respecting the properties of saccharin, a communication has been received from Dr. C. Fahlberg, of Saltsjö Westerhausen, traversing the statement that this article is injurious to the public health, and enclosing a pamphlet entitled "A Vindication of Saccharin," in which the opinions are quoted of various medical authorities as to the harmlessness of the article in question.

SACCHARIN IN BELGIUM.

A commission appointed by the Belgian Academy of Medicine have come to the conclusion that saccharin cannot be considered a substitute for sugar in aliments; but that, although differently borne by different subjects, it is not poisonous. They are of opinion also that it is not wholly voided out through the urine, and is liable to find its way into the milk and saliva. Consequently the Commission have reported that in their judgment all persons selling wholesale or retail articles sweetened with saccharin should be compelled to indicate the fact in a conspicuous manner.—*Chemist and Druggist*.

THE MANURE ACT.

Last February the French Parliament passed a law respecting the sale of fertilisers which in many ways resembles the British legislation governing the same subject. The new law on January 11 received its first application in the case of Samson and Cie., manufacturers of artificial guano. The firm, through their agent, one Millaud, sold to one Lanosa 100-kilo, bag of manure labelled and billed "Guano compost; 2 per cent. nitrogen, 10 to 15 per cent. phosphates." Lanosa complained that the article was wrongly described. Specimens were analysed by expert chemist Lhoté, who reported the fertiliser to contain 2'42 per cent. of nitrogen and 17'85 of phosphates, but to be an artificial compound in no way equal to natural guano. The defence set up was that the article had not been described as guano, but as "guano compost," that is, a compound of like value. The Seine Correctional Tribunal held that the word "guano" had evidently deceived Lanosa into buying the article, and that the provisions of the law had been violated. In consequence, Millaud was sentenced in two fines, 50 francs and 11 francs respectively, and costs. Civil damages will also probably follow as a matter of course.—*Chemist and Druggist*.

DAVID T. DAY,
Chief of Division of Mining Statistics,
U.S. Geological Survey, Washington.

THE KAINITE SYNDICATE.

Chem. Zeit. 12, 1723.

The owners of the potash mines in the Stassfurt district have formed a new syndicate for a term of ten years. The production of raw salts is distributed among the different mines, thus:—

	Carnallite.		Kainite.	
	To be Worked up into KCl and K_2SO_4 .	For Agricultural and other Purposes.	To be Worked up into KCl and K_2SO_4 .	For Agricultural and other Purposes.
	Per Cent.	Per Cent.	Centners.	Per Cent.
Royal Prussian Mines, Stassfurt	18½	20	1,300	18½
Ducal Anhalt Mines, Leopoldshall	18½	20	1,300	18½
Consolidated Alkali Works, Westeregeln	14½	10	800	15
Neustassfurt Company, Löderburg	14½	30	1,800	18½
Potash Works, Aschersleben	14½	5	2,000	18½
Ludwig II. Co., Stassfurt	10½	10
Potash Works, Nenenburg	7½	5	..	12½

The normal output amounts to 7,200 centners, about 360 tons per day.—S. H.

PERUVIAN GUANO.

The imports into Europe during the past six months amount to about 14,000 tons. The shipments from Peru seem to be on a very limited scale and point to the probability that the deposits are about exhausted.—*W. Montgomery & Co.*

DISCOVERY OF KAOLIN IN SWEDEN.

The Swedish *Post-och-Tidnings*, for 11th December last, announced the discovery of a bed of kaolin of unprecedented wealth in the island of If. In ploughing the land, a layer of excellent chalk was brought to light, and while a geological survey was being made of this chalk, a lower layer of remarkably fine kaolin or porcelain clay was unearthed. Specimens of this clay, having been analysed at Lund, at Berlin, and in the chemical station at Christianstad, prove to be of singular purity. The large extent of this deposit, moreover, is of interest, as porcelain clay has hitherto been found in Sweden only in small quantities. It is expected that the factory which has already been prepared for the manufacture of articles from the If kaolin will prove a source of wealth to the province.

THE WORKING OF THE MERCHANDISE MARKS ACT.

See Board of Trade Journal for January, p. 86.

METHYLATED SPIRITS.

The latest returns issued by the Board of Trade disclose the fact that the number of gallons delivered from the bonded warehouses in the United Kingdom for methylating purposes has advanced from 430,617 gallons in 1886 to 505,231 gallons in 1887, and 508,717 gallons in 1888.—*Chemist and Druggist*.

THE DRAWBACK ON SPIRITS EXPORTED AS MEDICINES.

We understand that the following instructions have been issued to officers of Inland Revenue, so that those druggists who contemplate exporting alcoholic medicinal preparations will find no difficulty in availing themselves of the general order issued in November 1888. We also hear that the authorities are considering further extension of facilities which are the logical outcome of those recently granted:—"Collectors are now authorised to grant compounders' licences to makers of medicinal spirits, notwithstanding that they use methylated spirits or keep stills for chemical purposes, on condition that the licence be used solely in relation to the preparation and export of medicinal spirits, under the general order of the 26th November last. Subject to this condition, the ordinary regulations applicable to rectifiers and compounders using stills need not be insisted on in regard to such persons. Collectors will take care to make any trader to whom a licence is issued aware of these conditions."—*Chemist and Druggist*.

Estimated consumption United Kingdom, 12,000 bottles per annum.

January, 1889.

—A. S. Pickering, Mining Lane, E.C.

The production of this metal seems to have been stationary during 1888 as compared with 1887, although several of the component items have varied a little. The increase of importations into United Kingdom to 69,167 bottles for the season ending 30th November, as against 59,811 bottles in the previous season, may therefore be attributed to California and China denuding themselves of stock, an operation that cannot be repeated this year. In fact, we expect this year's imports will be smaller than for many years past, because a serious accident at the Spanish Almaden mine will diminish the supplies from that quarter to a very considerable extent.

The exports have fallen off by about 18,000 bottles, which cannot be accounted for by any actual diminution in real consumption, so we fully expect a very material improvement in the statistical position will be developed during this current year. The market rates, owing to the exceptionally small exports and large imports previously referred to, have had a downward tendency, and would have fallen to a very low point had it not been for the exceptional firmness of the importers of Spanish, who for the past three months have rigidly maintained the price of 9l. 10s., against sales in the open market at very irregular quotations, at one time touching 7l. 17s. 6d., and to-day being about 8l. 5s. But of course, this action is putting them into a position to control the rates later on, when timid speculative holders are cleared out.—*W. T. Sargent & Sons' Annual Circular*.

LEAD.

There is again a material increase in the imports, and a small increase in the out-turn of British mines. A considerable surplus has been created which is chiefly stored in London warehouses. There has been considerable speculative activity, both here and in New York. Frequent and continuous efforts have been made to secure control of the markets, but in face of increasing supplies there seems no sound reason for such a course, and so far as we have been able to gather considerable losses have been incurred by

the attempt, and at one moment, the failure of an important speculator in America, brought about something like a feeling of panic. But this has gradually disappeared, and the market has a steady appearance at the close, and a full consumption is confidently looked for during this year. A rise based on this will be satisfactory to all parties.

The present quotation is 13*l.* 2*s.* 6*d.*, and the average for 1888 was 13*l.* 12*s.* 6*d.*

Australia	200	350
Germany	704
Haiti—San Domingo	2,175	3,044
Brazils	1,290
Other countries.....	397	1,029	1,544
Total	238,572	223,111	283,415

—“Our Supply of Phosphates,” HERMANN Voss.

THE ANNUAL TARIFF OF PRICES AND DISPENSING CHARGES FOR PRUSSIA.

The annual tariff of prices and dispensing charges for Prussia just issued includes the names of some new remedies. It will probably be of interest to note the figures at which the pharmacist is to charge for these articles, while at the same time the list indicates the opinions of the compilers as to which of the recent introductions are likely to continue in demand:

	s.	d.
Camphoric acid.....	1 decrm.	0 6½
“ ..	1 grm.	0 2½
Pictonitric acid	10 grms.	0 2
Creolin (liquor antisepticus Jeyes)...	10 ..	0 1½
“ ..	100 ..	0 8
Camol.....	10 ..	0 2
Guaicol.....	1 grm.	0 2
Phenacetin	1 ..	0 3
Sozoidol (sodium and potassium)...	1 ..	0 4
Sulphonal	1 ..	0 3
“ ..	10 grms.	2 11
Thalin tartrate	1 decrm.	0 6½

With regard to manipulations the only novelty is the inclusion of a price for compressing medicines. For one tablet, including all the necessary operations, a charge of 1*d.* is allowed. The other changes are of slight importance.—*Chemist and Druggist.*

THIOL.

Ichthylol has a rival in the field under the name of "Thiol." This is a patent preparation made from the paraffin oils obtained in the distillation of peat. According to the specification oil is heated to about 215° C., and a certain quantity of sulphur is added. Sulphuretted hydrocarbons are formed with disengagement of sulphuretted hydrogen. From the former the sulpho-acids are formed by the action of concentrated sulphuric acid, and from the acids the various salts are prepared. Trials have been made with the sodium and ammonium salts in the Clinic, Berlin, by Dr. Reeps; and it is said that in several cases thiol has been found equal to ichthylol therapeutically, and only slightly different from it in chemical and physical properties.—*Chemist and Druggist*.

TRADE BETWEEN SPAIN AND THE UNITED KINGDOM.

IMPORTS INTO THE UNITED KINGDOM FROM SPAIN.

PRINCIPAL ARTICLES.	Three Months ending	
	Dec. 1887.	Dec. 1888.
Chemical products unenumerated, Value £	17,532	12,811
Copper ore and regulus	£ Tons 17,866	25,528
	£ Value £ 375,447	573,974
Manganese ore	£ Tons 2,180	1,810
	£ Value £ 3,190	5,520
Pyrites of iron or copper	£ Tons 118,101	136,588
	£ Value £ 225,889	282,582
Quicksilver	£ Lbs. 12,603	193,782
	£ Value £ 1,290	50,000

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

1888.

18,749. W. Matthews and J. Yates, Manchester. Apparatus for producing spray. December 22.

18,750. M. Smith, Manchester. Apparatus for supplying fuel to boiler and other furnaces. December 22.

18,783. H. J. Hodges and W. T. Ramsden. See Class XVII.

18,808. W. A. Richards, Liverpool. Improvements in or apparatus relating to centrifugal filters. December 21.

18,860. H. J. Allison.—From the Casamajor Filter Co., United States. Apparatus for cleansing filtering media. Complete Specification. December 27.

18,917. E. K. Muspratt and J. H. Lewis, London. Improvements in apparatus or vessels for use in the absorption of gases by liquids. December 27.

18,918. V. Popp, London. Improved methods and apparatus for utilising compressed air for the production of cold. December 28.

18,951. G. C. Dymond.—From the Aerated Fuel Co., United States. Improvements in or relating to furnaces for utilising hydrocarbon as fuel, and in burners and operating devices applicable therefor. December 28.

18,957. R. Poole Roe, Liverpool. Improvements in apparatus for filtering water and other liquids. December 28.

19,057. E. Dobson, London. Improvements in apparatus or appliances for consuming or preventing smoke in furnaces. December 31.

1889.

34. T. Skitter, London. Improvements in apparatus for evaporating liquids. January 1.

81. W. Lawrence, London. Improvements in apparatus for distillatory and other purposes. January 2.

490. F. H. Danchell, London. Improvements in means or apparatus for separating solid matters from liquids. January 10.

676. P. de Mol and A. Gerken, London. Improvements in filters. January 14.

681. The Native Guano Co., Limited, and C. E. Robinson, London. Improvements in apparatus for measuring liquids. January 14.

785. H. H. Lake.—From J. M. Duncan, United States. Improvements in apparatus for evaporating brine, and for similar purposes. Complete Specification. January 16.

824. H. B. Higginson.—From H. P. Higginson, New Zealand. Improvements in or connected with apparatus for compressing air. January 16.

900. Fleming's Oil and Chemical Co., Limited, and G. H. Fenner. See Class II.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

1888.

18,678. F. R. Jones, Huddersfield. A new or improved method of and means for preventing the emission of smoke from mill or other chimneys. December 21.

18,682. W. J. Righton, London. Improvements in instantaneous water-heaters. December 21.

18,692. H. Darby, London. Improvements in apparatus for generating and burning gases from hydrocarbon oil and water. December 21.

18,950. J. R. Wicham, London. Improvements in illuminants for lighthouses, beacons, and like places. December 27.

18,918. J. Nimmo and J. Scotland, Glasgow. Improvements in the manufacture of coke, and in the ovens and apparatus employed therefor. December 27.

18,951. G. C. Dymond.—From the Aerated Fuel Co. See Class I.

1889.

50. C. F. Claus, London. Improvements in the production of mixtures of hydrogen and carbonic oxide, and in obtaining hydrogen, carbonic oxide or carbonic acid, each severally; also obtaining certain by-products. January 1.

90. S. G. Rhodes, London. Improvements relating to "fire-balls" for use as artificial fuel in gas stoves and grates. January 2.

111. W. F. Richards, Glyncollen. Improvements in the treatment of anthracite small coal or culm. January 3.

248. R. Clark and J. W. T. Stephens, Cardiff. Improvements in the manufacture of artificial fuel. January 5.

329. T. Wrench, Liverpool. Improvements in firelighters. January 8.

411. J. S. Chapman, London. Improvements in appliances and compositions to be used therewith, for lighting fires, and other lighting purposes. January 9.

531. E. Pierce and F. Mirks, Manchester. Improvements in appliances for and method of increasing the illuminating power of gas, oil, and similar lights. January 11.

599. J. T. Key, London. The manufacture of gas from water for manufacturing, illuminating, and other purposes. January 12.

703. H. S. Maxim, London. Improvements in and relating to apparatus for carburetting gas. January 14.

768. J. O. Spong, London. An improved construction of gas-carburetting apparatus. January 15.

900. Fleming's Oil and Chemical Co., Ltd., and G. H. Fenner, London. An improved construction of moulds for casting rectangular slabs of naphthalene or like material. Complete Specification. January 17.

905. W. B. Westlake, Swansea. Improvements in machinery or apparatus for the manufacture of perforated fuel. January 19.

1011. W. B. Westlake. Improvements in machinery or apparatus for the manufacture of perforated fuel. January 19.

COMPLETE SPECIFICATIONS ACCEPTED.*

1887.

17,799. H. Hutchinson, London. Apparatus for generating gas. January 2.

1888.

14,925. W. T. Walker. Apparatus for the purification of coal gas. January 2.

15,995. R. H. Michell. Method and means for consuming smoke and economising fuel. January 2.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, ETC.

COMPLETE SPECIFICATION ACCEPTED.

1888.

6341. J. Imray.—From J. Bartsch, Germany. Treatment of coal to obtain separate products therefrom, and apparatus therefor. January 2.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

1888.

18,709. E. Edwards.—From Standert Brothers, Belgium. A new or improved blue dye. December 21.

18,859. J. H. H. Richez, London. Improvements in the manufacture of aniline blue. December 21.

1889.

16. A. Deninger, London. Improvements in the preparation of nitro and amido phenols from the corresponding amides. Complete specification. January 1.

388. W. G. Thompson and A. Rée, Middleton, Manchester. A new process for the manufacture of soluble colouring matters. January 9.

1046. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in and connected with the manufacture and production of unsymmetrical acid green. January 19.

COMPLETE SPECIFICATION ACCEPTED.

1888.

9280. C. Dreyfus. Production of new colouring matters for dyeing and printing. January 2.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATION.

1889.

66. H. W. Langbeck, Longton. A process for separating and utilising all valuable matter obtained by washing wool in various ways. January 2.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

1888.

18,717. E. O. Fankbanser, London. A new mordant for dyeing purposes. Complete Specification. December 21.

18,773. R. P. Frist, London. Improvements in linings for bleaching keirs, vats, dye tanks, and other analogous receptacles. Complete Specification. December 22.

18,780. H. Recker, London. An improved process of and apparatus for dyeing cotton yarn. December 22.

18,877. T. Fox Naylor and A. Naylor, Kidderminster. Dyeing banks of yarn. December 27.

18,904. J. Cowan, Glasgow. Improvements in and connected with indigo dyeing. December 27.

18,987. J. Pollard, Manchester. Improvements in apparatus for washing, scouring, bleaching, dyeing, and otherwise similarly treating textile fabrics. December 29.

1889.

197. J. Inray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, France. A process for dyeing with yellow, orange, and red azoic colouring matters. January 1.

216. W. Bracewell, Brinscail, Lanc. Improvements in apparatus for keirs used in bleaching and dyeing. January 5.

350. W. Mather.—From V. G. Bloede, United States. A process for tinting fabrics with fast colours. January 8.

351. W. Mather.—From V. G. Bloede. Improvements in processes for colouring and finishing cotton and other cheap fabrics. January 8.

552. W. Mather.—From V. G. Bloede. Improvements in processes for colouring or tinting fabrics. January 8.

553. W. Mather.—From V. G. Bloede. Improvements in processes for tinting fabrics and fibres. January 8.

376. W. L. Wise.—From M. von Gallois, Germany. Processes for the manufacture of new chrome mordanting substances, and for the application thereof for dyeing and printing purposes. January 8.

415. A. G. Salamon, London. Improvements in the bleaching of fibre. January 9.

508. H. Smith, Halifax. Improvements connected with dyeing essels employed for dyeing cloth or other fabrics. January 11.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

1888.

18,921. R. H. Steedman and A. J. Kirkpatrick, Glasgow. Improvements in reconvertng and utilising by-products such as are formed in processes for obtaining chlorine. December 28.

19,023. E. W. Parnell and J. Simpson, Liverpool. Improvements in the method of treating alkaline sulphides in solution, or an aqueous mixture of the same with carbonic acid gas for the production of sulphuretted hydrogen, and in apparatus therefor. December 31.

1889.

94. J. Hargreaves, T. Robinson, and J. Hargreaves. See Class IX.

214. R. Hodgson, Birmingham. A new or improved method of and apparatus for the manufacture of salt from brine by hot air and steam. January 5.

382. M. Williams, Liverpool. Improvements in the manufacture of barytes. January 9.

778. F. Maxwell-Lyte, London. Improvements in the production of chlorine and of hydrochloric acid. January 15.

881. R. H. Steedman and A. J. Kirkpatrick, Glasgow. Improvements in obtaining chlorine, and in reconvertng and utilising by-products of the processes. January 17.

1007. O. E. Pohl, Liverpool. Improvements in the manufacture of salt, and in apparatus and appliances employed therein. January 19.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

2920. F. Maxwell-Lyte. Production of basic lead salts for use as pigments and for other purposes. January 2.

3218. F. H. Gossage and T. T. Mathieson. Manufacture of the sulphides of sodium and potassium from their respective sulphates. January 2.

15,980. H. Albert, C. Fellner, and C. Ziegler. Apparatus in combination with furnaces for roasting pyrites, &c., containing sulphur, for obtaining the sulphurous gases given off therefrom. January 2.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

1888.

18,810. H. Faulkner, Walton-on-Thames. The imitation of polished marbles, granites, and other stones, and for the imitation of glazed tiles. December 24.

1889.

153. J. B. Adams, Barnsley. A method of and apparatus for making glass ball stoppers and solid or hollow articles from molten glass or suitable plastic or molten material. January 1.

161. T. Willett, London. Improvements in and machinery or apparatus for manufacturing plates and other articles in earthenware, china, and other plastic materials. January 1.

308. J. Hill and T. Hill, Fenton. A substitute for plaster of Paris in use for potters' moulds. January 8.

593. W. H. Grindley, Tunstall. Improved thimble for the placing of china and earthenware in enamelling kilns and glost oven saggars. January 12.

644. W. B. Fitch, London. Improvements in the manufacture of glass bottles and similar articles. January 12.

959. H. J. Haddan.—From the Josephine Glass Works, Germany. A process for the manufacture of glass resembling crystal, containing petrified moss or the like. January 18.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

1751. J. B. Gormeil-Bonmand. Production of designs on china, earthenware, and glass. January 2.

2184. E. Story and R. Panshon, London. Manufacture of glass. January 2.

16,153. J. Syer. Silvering glass. January 2.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

1888.

18,708, E. Edwards.—From F. Meyer, Germany. Improvements in waterproof roofing material. Complete Specification. December 21.

18,712, J. B. Spence, London. Improvements in the preservation of wood and other fibrous materials. December 22.

18,771, W. Millar, G. M. R. Layton, and T. Grover, London. Improvements in or relating to fire-proof building construction. December 22.

18,806, F. Hunsinger, London. An improved roofing tile. Complete Specification. December 27.

19,010, G. H. Sharpe and F. W. Turner, London. Improved manufacture of cement suitable as plaster, and for moulding purposes. Complete Specification. December 29.

1889.

91, J. Hargreaves, T. Robinson, and J. Hargreaves, Liverpool. Improvements in the treatment of lime refuse from alkali works to render it suitable for the manufacture of cement, and in apparatus employed therein. January 3.

116, R. Stone, London. Improvements in the manufacture and utilisation of cement and plaster, and in the machinery and appliances therefor. January 3.

961, C. J. Widmark, London. Improvements in the manufacture of cement. Complete Specification. January 18.

COMPLETE SPECIFICATION ACCEPTED.

1888.

1978, W. Joy. Manufacture of cement, and apparatus therefor. January 2.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

1888.

18,792, J. Clark, Birmingham. Improvements in obtaining aluminium and its alloys. December 22.

18,823, J. A. B. Bennett, Birmingham. Improvements in the manufacture of aluminium from aluminium sulphate or alums. December 24.

18,842, L. L. Burdon, London. Ingots for making seamless plated wire. Complete Specification. December 24.

18,919, B. Willeox.—From La Société Anonyme le Ferro-Nickel, France. Improvements in the manufacture of iron and steel alloyed with other metals. December 27.

18,928, W. Clifford, Sheffield. Improvements in the construction of safety-lamps for mines. December 28.

1889.

7, A. G. D. Cranshaw, London. Improvements in the manufacture of steel chain. January 1.

28, A. B. Cunningham.—From H. Havemann, France. Improvements relating to the extraction of gold, silver, and lead from substances containing the same, and to apparatus therefor. January 1.

77, E. A. Billault, London. The manufacture of jewellery, gold, and silversmiths' ware, buttons, and other ornamental objects for dress, furniture, &c., from sulphide of silver. January 2.

157, M. Breslauer, London. An improved alloy to serve as a substitute for silver. January 4.

149, J. W. Summers, Staleybridge. Improvements in the process of working scrap metal. January 4.

160, P. Evans, Liverpool. An improved coating for iron or steel and other metal plate, pipes, and other articles, and modes or means of and apparatus employed in the coating of such materials or articles. January 4.

187, P. M. Parsons, London. Manufacture or production of metallic alloys. January 4.

256, L. P. H. J. Mauchaire, London. Improved means and apparatus for treating gold, silver, and other ores. January 7.

281, A. B. Cunningham, London. Improvements in the manufacture of sodium and potassium. January 7.

311, S. Pope and J. Duce, London. Improvements in armour plates for ships and other structures. January 8.

322, W. Key, Glasgow. Improvements in and relating to gas furnaces, applicable for smelting and other purposes. January 8.

336, E. Britton, Birmingham. Improvements in boxes known as "box piles," to be employed in the converting of iron or steel scrap into bar or plate. January 8.

339, R. A. Hadfield, London. Improvements in the manufacture of steel. January 8.

345, C. N. B. Wetzelar.—From W. L. Carl, United States. A portable prospecting machine for use in mining and working on the dry process. January 8.

359, C. Netto, London. Improvements relating to the extraction of aluminium from cryolite and other substances. January 8.

477, A. G. Greenway, Liverpool. Improvements in the manufacture of zinc from hard spelter, zinc-iron, or galvanisers' dross. January 10.

590, G. Gatheral, London. Improvements in the treatment of copper precipitates. January 11.

597, S. O. Cowper-Coles and W. A. Thomas, London. Coating metals or their alloys with platinum. January 12.

659, C. A. Burghardt, Manchester. Improvements in the reduction of zinc and tin from their ores. January 14.

668, J. Wallis, Sheffield. Improvements in the manufacture of iron and steel, iron and steel forgings and castings. January 14.

739, R. S. Casson, London. Improvements in and connected with the casting of metals. January 15.

812, R. A. Hadfield and A. G. M. Jack, London. Improvements in the manufacture of common and other cast steel shells. January 16.

841, J. B. Haunay, London. Improved means of extracting precious metals from ores. January 16.

843, J. H. Selwyn, London. Improvements in hydro-metallurgical processes. January 16.

868, J. Hart, Middlesbrough. A new method of heating plates of steel, iron or any other metal. January 17.

890, R. Stanfield and T. Clarkson, London. An improved method and means for separating metals and heavy minerals from ores. January 17.

971, J. Y. Johnson.—From A. Imbert, France. Improvements in or connected with the reduction of metallic oxides, and the means or apparatus employed therein. January 18.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

3071, J. Pearson. Miners' safety-lamp. January 2.

11,340, H. Ostermann and C. Lacroix. A new metallic alloy. January 2.

11,941, H. Ostermann and C. Lacroix. A new non-magnetic metallic alloy. January 2.

14,511, W. H. Jenkins. Mining drills. January 2.

16,063, F. Tribbensee. Process for coating copper, iron, and other metallic vessels with lead. January 2.

16,872, A. Ritter von Klinkosch and I. Ritter von Klinkosch. Process and apparatus for making spoons and forks of silver and other metals and alloys. January 2.

17,270, M. Graff. Manufacture of steel. January 2.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

1888.

18,751, G. C. Dymond.—From C. Gassner, Germany. Improvements in or relating to galvanic batteries. December 22.

18,858, F. J. Brougham.—From La Société Perreux-Lloyd et fils, France. Improvements in electro-chemical generators. December 24.

18,881, L. Reuleaux, London. Improvements in the preparation of materials which have to be submitted either to voltaic heat or to electric heating, combined with electrolysis. December 27.

18,968, E. L. Zalinski and H. J. Smith. See Class XXII

18,978. T. W. Bush, Broseley. An oblique meshed grid plate for storage batteries. December 29.

18,981. M. Doubleday, Nottingham. An inner expanded chamber grid plate for storage batteries. December 29.

18,991. M. Doubleday, Nottingham, and T. W. Bush, Broseley. A bent plate storage battery. December 29.

18,991. G. C. Dymond.—From J. M. A. G. Lésenyer, France. Improvements in and appertaining to the manufacture of metals or metallic alloys by means of electricity. December 29.

19,034. W. J. S. Barber-Starkey, Manchester. Improvements in secondary voltaic batteries. December 31.

19,047. R. W. Hewett. See Class XVI.

19,058. J. Y. Johnson.—From F. Gendron, France. Improvements in electric batteries. December 31.

19,061. A. Cornwell, London. An improvement in materials to be used in galvanic batteries. December 31.

1889.

85. A. Poleschko, London. Improvements in dynamo-electric machines. January 2.

126. G. B. Luckhoff, London. An improvement in or relating to dynamos. January 3.

319. W. P. Kookogey, London. Improved apparatus and connections for charging and discharging storage batteries. Complete Specification. January 8.

320. W. P. Kookogey. Improved methods of preparing solution compounds for galvanic batteries. Complete Specification. January 8.

361. H. H. Lake.—From E. Thomson, United States. Improved methods of and apparatus for welding, shaping, and otherwise working metals by the aid of electricity. Complete Specification. January 8.

362. H. H. Lake.—From E. Thomson. Improved methods of and apparatus for welding, shaping, and otherwise working metals by the aid of electricity. Complete Specification. January 8.

377. H. H. Lake.—From E. Thomson. Improvements relating to the riveting of metal plates and other objects by the aid of electricity. Complete Specification. January 8.

435. J. H. Holmes, Newcastle-on-Tyne. Improvements in dynamo-electric machines. January 9.

485. H. E. Newton.—From D. Piedrahita, France. Improvements in electric generators. January 10.

588. B. M. Drake and J. M. Gorham, London. Improvements in secondary batteries. January 12.

746. O. Lugo, London. Improvements in and relating to electric secondary batteries or accumulators. Complete Specification. January 15.

813. W. Diehl, London. Separation of aluminium and its alloys from its fluorides by electric or by chemical metallurgic process. January 16.

907. T. Cuttriss, Leeds. Improvements in secondary or storage batteries. January 19.

1031. J. W. King, London. Improvements in dynamo-electric machines. January 19.

COMPLETE SPECIFICATION ACCEPTED.

1888.

8700. L. M. J. C. C. Renard. Electric batteries. January 2.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

1888.

18,782. R. Stone, London. Improvements in the manufacture of soap. December 22.

18,852. H. H. Lake.—From La Société Anonyme des Parfums Naturels de Cannes, France. Improvements relating to the purification of fatty substances, and to apparatus therefor. December 21.

18,857. H. H. Lake.—From La Société Anonyme des Parfums Naturels de Cannes. Improvements relating to the purification of fatty substances, and to apparatus therefor. December 21.

18,934. R. Hunt, Liverpool. Improvements in the purification of cotton-seed, rape-seed, and linseed oils, and foots and discoloured greases. December 28.

19,015. G. T. Bishop, London. Improvements in apparatus to be employed in the manufacture of soap. December 29.

1889.

854. F. W. Longhurst, London. Improvements in the manufacture of soap. January 16.

903. O. Hehner, London. A process for removing odour and taste from oils and fats. January 17.

COMPLETE SPECIFICATION ACCEPTED.

1888.

2971. W. T. Lawson. An improved compound for washing purposes. January 2.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

1888.

18,705. H. B. Condy, London. Improvements in or relating to the manufacture of white lead. December 21.

18,716. C. Morfit, London. An improvement in the manufacture of resin liquor for paper makers and others. December 21.

1889.

722. J. Y. Johnson.—From G. Fell, New York. Improvements in the manufacture or production of lead pigments. Complete Specification. January 15.

847. E. Edwards.—From A. E. Mornard, France. An improved composition for facilitating the application and preservation of paint or varnish upon cement or other materials. January 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

2920. F. Maxwell-Lyte. See Class VII. January 2.

5399. R. Stone. Manufacture of paint. January 2.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

1888.

19,002. E. Edwards.—From J. E. Pechinot, France. Improvements in the utilisation of leather, and in its treatment for the purpose of such utilisation. December 29.

1889.

645. H. E. Frendenberg, London. Improvements relating to the treatment of hides and skins, and to apparatus therefor. January 12.

880. H. Belcher, London. Improvements in the treatment of skins and hides for the preparation of leather. January 17.

XV.—AGRICULTURE, MANURES, Etc.

APPLICATIONS.

1888.

18,905, P. M. Justice.—From W. J. Williams, United States. Improved method of manufacturing nitrogenous fertilisers from phosphates of iron and alumina. Complete Specification. December 27.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

1888.

18,722, W. T. Crooke, Stratford. Improvements in pockets or bags employed in the manufacture of sugar and like substances, together with an improved process for cleansing the same. December 22.

18,872, E. J. Ball, London. Improvements in the manufacture of sugar. December 26.

18,952, C. D. Abel.—From E. Kiderlen, E. Kiderlen, jun., and J. W. Van Leenhoff, Holland. Improved treatment of syrups for the removal of impurities therefrom. December 28.

19,347, R. W. Hewett, Handsworth. A new or improved method of refining sugar by electricity. December 31.

1889.

75, O. Lenz, London. Process for manufacturing crystallised maltose. Complete Specification. January 2.

76, O. Lenz. Process for manufacturing colourless maltose syrup. Complete Specification. January 2.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

1888.

18,783, H. J. Hodges and W. T. Ramsden, London. Improvements in cooling beer and other liquids, and apparatus connected therewith. December 22.

1889.

83, W. Lawrence. See Class I.

86, O. Inray.—From A. Bergh, Denmark. Improved process for aerating and purifying beer worts and beer, and apparatus therefor. January 2.

221, A. Perry, London. Improvements in the treatment or preparation of rice and other grain or cereals for brewing and other purposes, and in means or apparatus employed therein. January 5.

770, H. E. Sorel, London. Improvements in the treatment of commercial alcohols. January 15.

883, H. MacLagan, New York. Distilling volatilisable liquids from a mash or mixture. January 17.

962, A. Malzy, London. Improved alcoholic beverages. January 18.

COMPLETE SPECIFICATION ACCEPTED.

1888.

16,885, H. H. Lake.—From J. W. Free. Apparatus for the manufacture of malt. January 2.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—CHEMISTRY OF FOODS.

1888.

19,009, J. L. Johnston, London. Further improvements in the preparation and combination of animal substances for use as food. December 29.

1889.

163, E. Pott, Munich. The preservation of eggs and of all other articles of food. January 1.

163, H. S. Wellcome, London. An improved dry preparation of tea or coffee. January 4.

255, G. Christopher and R. W. Leftwich, London. Improvements in the preparation of the extracts of tea and coffee. January 7.

771, G. D. Wheaton, London. Improved means of effecting the preservation of materials of a perishable nature. January 15.

1033, W. G. Pursell, Glasgow. Improvements in and relating to the treating and preserving of fish. January 19.

B.—SANITARY CHEMISTRY.

1888.

18,719, W. Warner, London. Improvements in the means of and apparatus for treating refuse. December 21.

18,791, J. Chabanel, London. Improved apparatus for separating, filtering, and disinfecting fecal matters. December 22.

1889.

412, U. A. Smith, London. An improved system of sewerage. January 9.

413, U. A. Smith. An improved system of sewerage. January 9.

C.—DISINFECTANTS.

1888.

18,775, W. B. Giles, A. Shearer, and F. G. A. Roberts, London. Improvements in the manufacture or production of bisulphite and meta-bisulphite of sodium or potassium. Complete Specification. December 22.

1889.

204, R. Hannan and W. Paterson, Glasgow. Sanitary ink, being an antiseptic and deodorising compound for application to paper or any other material in printing or otherwise. January 5.

397, R. Hannan and W. Paterson. See Class XIX.

COMPLETE SPECIFICATION ACCEPTED.

A.—CHEMISTRY OF FOODS.

1888.

2426, W. Peacock. Apparatus to be employed in effecting the preservation of fruit, meat, fish, or other perishable articles of food. January 2.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

1888.

18,690, E. N. Hilher and J. C. Hetherington, London. Improvements in the manufacture or treatment of paper for copying letters and other documents. December 21.

18,693, G. Fry, London. An improved apparatus for washing paper pulp and similar substances. December 21.

18,716, C. North. See Class XIX.

18,753. L. Pictet, London. Improved method of sorting the disintegrated wood for the manufacture of cellulose, and apparatus therefor. December 22.

18,765. J. C. Hetherington.—From E. Rammerstein, Austria. Improvements in the manufacture or treatment of paper for copying letters and other documents. December 22.

18,795. W. Searle, London. Improvements in the preparation of paper to be used for copying letters and other writing. December 22.

1889.

108. C. Herbert, Glasgow. Improvements in apparatus for cleaning, staining, and pressing paper pulp or similar pulp. January 3.

295. H. J. Medbury, Glasgow. Apparatus for manufacturing tubes, pipes, and like articles from pulp. Complete Specification. January 8.

363. W. H. Cook, London. A novel application of pulped paper stock. Complete Specification. January 8.

397. R. Hannan and W. Paterson, Glasgow. A sanitary paper being deodorising and disinfectant. January 9.

COMPLETE SPECIFICATION ACCEPTED.

1888.

17,227. H. H. Lake.—From C. H. Atkins. Apparatus for removing metallic particles from paper pulp. January 2.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATION.

1889.

741. A. F. Y. Schwartz and F. H. Mercklin, London. Improvements in the production of films sensitive to light, and of materials for assisting or continuing the effect of light on photographic films. January 15.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

1888.

18,366. A. Melville, London. Improvements in the manufacture of explosive mixtures. December 28.

18,367. A. Melville, London. Improvements in the manufacture of explosive mixtures. December 28.

18,968. E. L. Zalinski and H. J. Smith, London. Improvements in, and relating to electric primers or igniters for blasting or firing mines, torpedoes, projectiles, guns, and the like. December 28.

1889.

39. A. Martin, London. Improvements in percussion fuses for explosive projectiles. January 1.

236. R. S. Lawrence, London. Improved methods or means of treating high explosives, such as dynamite, and for the utilisation, protection, and firing of such explosives in projectiles, torpedoes, cartridges, and the like. January 5.

511. T. Martin, "La Fosse Andre," Guernsey. Improvements in rifle cartridges, time fuses, and the development of explosives in charges. January 11.

635. R. H. Heenan, London. Improvements in apparatus for charging cartridges with pulverulent explosive. Complete Specification. January 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

1439. A. V. Newton.—From A. Nobel. Explosive compounds. January 2.

1470. A. V. Newton.—From A. Nobel. Manufacture of safety fuses. January 2.

2723. J. Pann. Ships' signal lights and similar fireworks. January 2.

NOTICES.

Members who require back numbers are requested to make application only to the General Secretary.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

Notice is hereby given, for the information of subscribers for this Journal, that Messrs. EYRE and SPOTTISWOODE, Her Majesty's Printing Office, East Harding Street, London, E.C., have been appointed sole agents for the supply of the Journal to non-members and the trade.

IMPERIAL INSTITUTE.

The following BALANCE SHEET in regard to SUBSCRIPTIONS from FELLOWS of the CHEMICAL SOCIETY, INSTITUTE of CHEMISTRY, and SOCIETY of CHEMICAL INDUSTRY to the IMPERIAL INSTITUTE, has been furnished to the SOCIETY by DR. W. J. RUSSELL, F.R.S., Treasurer to the Fund.

	£ s. d.		£ s. d.
Subscriptions received from March 2nd, 1887, till July 14th, 1888.....	364 4 0	Printing circulars, notices, &c.	28 13 6
		Stationery	0 11 11
		Treasurer's stamps and drafts	0 11 2
		Bank charges on drafts	0 2 6
		Balance paid to Imperial Institute.	334 4 11
	<u>£364 4 0</u>		<u>£364 4 0</u>

Certified as correct,

F. A. ABEL,
Organising Secretary,
Imperial Institute.

W. J. RUSSELL,
Treasurer.
February 6, 1889.

LIST OF MEMBERS ELECTED, 22nd FEBRUARY, 1889.

Adamson, G. P., Easton, Pa., U.S.A., manufacturing chemist.
Baker, Jno. T., Easton, Pa., U.S.A., manufacturing chemist.
Bull, Henry J., 18, Ezerion Terrace, Ardwick, Manchester, chemist.
Burlon, J. Montague Chas., Mostyn Street, Llandudno, North Wales, pharmaceutical chemist.
Chaster, Jno. E., 13, West Scotland Street, Kinning Park, Glasgow, electro-chemical engineer.
Clapperton, Jas., 25, Queen Square, Regent Park, Glasgow, chemical student.
Cockrell, E., Gordon, 17, Grosvenor Chambers, Deansgate, Manchester, oil manufacturer.
Coffey, Eneas H., 111, Grosvenor Road, Pimlico, S.W., distiller.
Cooper, Astley, The Terrace, Beeston Hall, Leeds, analytical chemist.
Fuller, Chas. D., Braddock, Pa., U.S.A., chemist to Edgar Thompson furnaces.
Gee, W. W., Haldane, Owens College, Manchester, lecturer on physics.
Glossop, W. Dale, 93A, Portland Street, Manchester, paper merchant.
Hay, Alex., Kirby Villa, Arboretum Avenue, Lincoln, manufacturing chemist.
Hopkins, Thos. J., Cradle Bridge Works, Trowbridge, Wilts, engineer.
Klipstein, August, 52, Cedar Street (P. O. Box 2833), New York, U.S.A., chemical manufacturer.
Leach, Walter, Stephenson's Buildings, Sunbridge Road, Bradford, Yorks, analyst.
Low, Wilson H., c/o N. K. Fairbank & Co., 18th and Blackwell Streets, Chicago, Ill., U.S.A., chemist.
MacEwan, Peter, 42, Cannon Street, London, E.C., and 1, Gresley Road, Hornsey Lane, N., pharmacist and journalist.
Mawdsley, W. H., 8, Eaton Road, Chester, chemist.
Neil, Jas., c/o North British Chemical Co., Clydebank, Glasgow, assistant chemist.
Oldroyd, Geo. H., Sprinkwell Mills, Dewsbury, manufacturer.
Orchard, John, 100, High Street, Kensington, W., chemical engineer.
Richardson, S. M., 415, Main Street, Bonhill, N.B., analytical chemist.
Tasker, Geo., 2, Marchmont Terrace, Langside, Glasgow, analytical chemist.
Trechmann, A. O., Cliff Terrace, Hartlepool, analytical chemist.
Underhill, Thos. J., H. M. Victualling Yard, Deptford, S.E., clerk.

Walker, Jno. Cameron, 190, West Regent Street, Glasgow, analytical chemist.
Wesson, David, c/o N. K. Fairbank & Co., 225, 18th Street, Chicago, Ill., U.S.A., chemist.
Woolf, Mortimer, 3, Accl Road, West Hampstead, N.W., vinegar brewer.
Yule, Wm., Hendon Paper Works, Sunderland, analytical chemist.

SESSION 1888-89.

The Fifth Meeting of the Section will take place on Monday, March 4th, 1889.

Discussion.—"In what direction is State Aid needed to assist Technical Education in Chemistry?"

Messrs. Higgins and Heron's paper on "Cider" is postponed.

Monday, April 1st, 1889.

Dr. Percy F. Frankland. "The Action of Water on Lead."

Meeting held Monday, February 4th, 1889.

MR. DAVID HOWARD IN THE CHAIR.

APPARATUS FOR BOILING WITH REFLUX CONDENSER, AND DISTILLING WITHOUT ALTERING THE POSITION OF THE CONDENSER.

BY J. WALTER LEATHER, PH.D.

It is frequently required to first boil a liquid with an inverted condenser, and then to distil off some portion or the whole of the contents of the flask. The moving of the condenser to perform the second operation after the first has been completed, is always somewhat inconvenient, and, in order to avoid this, I have devised the following arrangement:—

The condenser is fixed perpendicularly, as in the above drawing. The lower end of the inner tube has a wide mouth, into which is inserted an india-rubber stopper. The distilling-flask is placed at the side (on the water-bath or tripod stand). Into the stopper of the latter pass two glass tubes. One of these, C, is bent obliquely towards the condenser, and passes through the centre of the india-rubber stopper of the condenser tube, and as far as the centre of the same. The other tube, A, which is bent parallel to C, is divided at the point D. It reaches only just to the upper surface of the condenser-stopper. The junction at the point D is (in the case of boiling with reflux condenser) made by means of a piece of thick-walled india-rubber tube. If, now, the liquid in the flask be made to boil, the vapour passes away up both the glass tubes into the condenser. By the one, C, it passes direct to the centre of the condenser, and the condensed liquid runs down towards the other tube. Vapour from the boiling liquid comes

also into the condenser by means of the other tube, A, but this tube acts in addition as a carrier of the condensed liquid back into the flask again.

When it is required to distil off any portion of the liquid in the flask, it is merely necessary to disconnect the tube A at D by sliding back the india-rubber joint, and to turn tube A round to any position, e.g., A', which may be convenient for connecting with the receiver. At the same time a small cap of india-rubber is fixed over the open end of the short tube at D. The boiling being recommenced, the vapour passes only through C into the condenser, and the condensed liquid passes out through tube A'.

MODIFICATION OF SOXHLET'S EXTRACTOR.

BY J. WALTER LEATHER, PH.D.

The ordinary form of Soxhlet's extractor is attached to the condenser by means of a cork. It is, however, frequently difficult to get good corks, some being so hard as to split the upper part of the extractor, while other descriptions are so porous as to permit the water, which generally collects on the condenser and trickles down to the cork, to enter and thus render the ether extremely wet.

For the idea of substituting a mercury connexion for the cork I am indebted to my friend Dr. Vieth, and I am now able, after several months' trial, to give a description of a mercury connexion which answers the purpose well. In the accompanying sketch, A is the lower part of the condenser, B is the Soxhlet's extractor. On to the lower end of the condenser tube I have had a bell-shaped mouth blown, which is just so wide that it passes readily over the upper end of the extractor, and the end of the condenser tube passes a short way inside the bell-mouth, so that the condensed ether drops directly on to the substance which is being extracted. At the upper part of the extractor is a piece of glass tube,

so wide that it passes readily over the bell-mouth of the condenser, and which is fixed at its lower part (that shaded in the drawing) to the extractor by means

of cement. An india-rubber ring also makes a good joint in place of cement, but it is generally difficult to get one the exact thickness. This wide tube, together with the extractor, forms a ring-cup into which the bell-mouth of the condenser may pass. The ring-cup is filled about half full of mercury and forms, when the extractor is pushed up under the condenser, a perfect joint. The extractor may be held in position by means of a clamp, or it may be readily suspended from the condenser by copper wire.

DISCUSSION.

The CHAIRMAN said that he had been greatly interested by the apparatus shown by Dr. Leather. Suggestions for the improvement of such apparatus were always welcome, especially if, as was always possible, they could be adapted to purposes other than those for which they were specially designed.

Mr. A. H. ALLEN then described the following improved form of condenser stand, devised by Mr. W. Chattaway and himself:—

which allowed the condenser to be reversed at any moment without disconnecting the distilling flask, while it permitted of the contents of the latter being agitated whenever desired. This was done by hanging the condenser from a stout leather thong which passed over three small brackets attached to a piece of wood working vertically in a slot in the stand. The thong could be fixed by means of a screw at the end of the centre bracket. In practice the arrangement had proved very efficient and convenient.

SOME INDUSTRIAL APPLICATIONS OF OXYGEN.

BY L. T. THORNE, PH D.

Now that the work carried out during the last few years, under the auspices of Brin's Oxygen Company, has resulted in the solution of the long-mooted problem of the preparation of oxygen on the large scale at a price which should bring it within the range of industrial applications, it may be of interest to call attention, very briefly, to one or two such applications which have up to the present been investigated.

But before entering on the consideration of these applications it will probably be well to refer, in a few words, to the present position of oxygen production. For though Boussingault's classical researches pointed undoubtedly to the atmosphere as the source for oxygen, and to barium oxide as the medium for its extraction, the practical difficulties of the process—one of the chief amongst which was the gradual diminution of the absorptive power of the oxide for oxygen—have hitherto prevented its being practically carried out.

The last-named difficulty having been overcome by taking special precautions to obtain the baryta employed in a suitable physical condition, and to suitably purify the air from carbonic anhydride and moisture, the further difficulties of economical heating and of converting a small laboratory experiment into a commercially practical process had to be grappled with.

As the present paper does not purport to be on the production of oxygen, but on its applications, it is unnecessary to follow the development of the process in all its details. Suffice it to say the difficulties have been so far overcome that, including all costs, the production of oxygen by this process will certainly not exceed 7s. 6d. per 1,000 cubic feet in London. In the manufacturing districts, where coal and labour is much less than in London, the cost will be reduced to about 5s., and in gasworks and other places, where special facilities as to fuel, power, &c. exist, the cost will be still further reduced.

The furnaces now in use are of several kinds, the retorts being placed in some horizontally, in others vertically. One recent modification, that may in many circumstances prove very advantageous, is the adoption of a constant temperature for the furnace and retorts.

The temperature employed lies between the temperature most suitable for oxydation and that most fitted for deoxydation, the air being pumped in during oxydation under a pressure of from 15 to 20 lbs. on the square inch, and the oxygen drawn off by means of a vacuum. Under these circum-

stances neither the oxydation nor deoxydation of the baryta is so complete as when varying temperatures are employed, and the yield of oxygen per operation is in consequence much smaller. Still the change of pressure is sufficient to determine a certain variation in the state of oxydation of the baryta, and this is aided to some extent by the cooling effect, during oxydation, on the baryta of the cold air pumped in. And though the yield of oxygen per operation is small—about 1 ft. per lb. of baryta used, against about 7 where the temperature is changed—the number of operations per day is so much increased, and the manipulation so much simplified, that this form of furnace will under most circumstances be more advantageous than the older form.

Turning now to the applications of oxygen, I would take the opportunity to apologise for bringing this subject before the Society in its present unfinished state. When at the beginning of the session I undertook to read a paper before you, I fully hoped that the chemical or theoretical side of the questions to be treated of would ere this have been worked out. Owing to press of work, however, the necessary laboratory experiments have not yet been completed. Nevertheless, I thought it best to lay before you the facts already ascertained, and trust at a future time to be allowed to return to the subject when further research has given more definite insight into the rationale of the various processes.

The use of Oxygen in Bleaching.

It is of course well known that in the bleaching of natural colouring matters by chlorous bleaching agents, the true bleaching agent is in almost all cases oxygen. But all attempts to employ free oxygen in the place of chlorine or chlorine compounds have hitherto proved unavailing, except perhaps in the open bleach-field, where the action of the oxygen is aided by sunlight. The opinion has therefore grown up that before oxygen can become an active bleaching agent, it is necessary for it to be in a nascent state, or at least in its active form of ozone. Experiments recently made have shown, however, that this opinion is only justified up to a certain point; for though all attempts to bleach by the action of free oxygen alone—whether at high or low temperature, or under normal or increased pressure—were unsuccessful, it was found that when used in conjunction with chlorine or bleaching powder, oxygen possesses a most decided bleaching power. The experiments were made with paper pulps—wood, straw, esparto, and jute or gunny—and also with raw jute, jute yarn and cloth, and cotton cloth. The results were similar in all cases, but since, as yet, the experiments on yarns and cloths have been confined to the laboratory, the remarks in the present paper will be mainly confined to the bleaching of paper pulps with which experiments have been carried out on a practical scale.

When a stream of oxygen was passed into a mixture of paper pulp and solution of bleaching powder, it was noticed that the de-colouration of the pulp proceeded much more rapidly than was the case when no oxygen was used. At first it was thought that this might be due to the mechanical stirring effect of the current of oxygen. A stream of nitrogen was therefore substituted for the oxygen, but the result was a retardation of the bleaching. A current of air was then tried, the effect being that the rate of bleaching was almost exactly the same as when bleaching powder solution was alone used. When equal volumes and strengths of solution and weights of

pulp were used, the residual liquid from the oxygen experiment always contained, after the bleaching was complete, more available chlorine than either of the others. It thus became clear that oxygen produced a beneficial, nitrogen a detrimental effect, whilst the apparent inaction of the air current was probably due to the effects of the oxygen and nitrogen neutralising one another.

Experiments were now undertaken in a closed churn, and it was found that when using about 28 lbs. dry pulp, mixed with a solution of bleaching powder, from 6 to 8 ft. of oxygen might be slowly passed into the churn without any increase of internal pressure being shown. When nitrogen was passed in, the pressure began to rise immediately, and when the excess of nitrogen was allowed to escape, it was found to be strongly charged with chlorine. When air was used the pressure rose steadily but more slowly than with nitrogen, and the excess of gas was found to contain but little oxygen, but to be strongly charged with chlorine. There could thus be no doubt that the oxygen was actually used up and helped to effect the bleaching, whilst the nitrogen was not only without bleaching effect, but when escaping from the liquid carried away with it part of the chlorine which is constantly being set free in a solution of bleaching powder. And even with oxygen the absorption was limited, and if too much was passed in or it was admitted too rapidly, pressure rose at once and the excess was not only useless but detrimental.

Further experiments showed that not only did a stream of oxygen accelerate the bleaching, but that it very considerably reduced the quantity of bleaching powder necessary. In a large number of experiments the saving of bleach which was effected ranged from 40 to 50 per cent., the saving being greater the finer the state of division of the oxygen on entering the pulp and the more intimately it was brought in contact therewith.

But it is one thing to make a laboratory experiment, another to carry the experiment into practice, and the above detailed results had yet to stand the test of practical working. Arrangements were therefore made to test the process on a large scale at a paper mill. Two large open potchers, each capable of carrying nearly a ton of straw or esparto, were fitted with a finely perforated tube running across the potcher just in front of the beater, and the whole of the pulp bleached in these two potchers during five days was treated, the total amount being over 50 tons of esparto, straw, &c. The conditions of the trial were disadvantageous to the process, since the potchers being open with only about 20 inches head of water, it was difficult to bring the oxygen intimately into contact with the grass and to prevent a large quantity of it escaping. In order to do this as far as possible, the above-mentioned position was chosen for the oxygen pipe, as the revolving beating cylinder then prevented the oxygen rising straight to the surface of the liquid, carried it forward, and did much to bring it into contact with the pulp. But, on the other hand, the strong bleach was run into the potcher on top of the pulp, &c., behind the beater, and it was about a quarter of an hour before it became well incorporated and reached the oxygen pipe, a large part having in the meantime been used up. But even under these conditions the effect of the oxygen was very marked, and the average saving of bleach was about 30 per cent., at a cost of about 200 cubic feet oxygen per ton of raw material treated. In a more permanent installation, where the oxygen and bleaching solution would be introduced side by side and the distribution of the oxygen improved,

the saving would undoubtedly be much larger and would probably reach that obtained in the laboratory experiments already detailed. This process may be applied at very little cost to almost all existing paper-bleaching plant, and besides the saving of bleach, decreases the damage to the fibre and thus produces a paper of increased tensile strength.

With chlorine, oxygen acts in the same way. Whether used for gas-bleaching, or whether the mixed gases are led into water in which paper pulp is suspended, a considerable quantity of oxygen is absorbed, and a saving of about 50 per cent. of chlorine effected. To give a single example, a glass chamber of 4.4 litres capacity was lightly filled with 200 grms. dry jute, slightly moistened, and was then made air tight, and connected with a retort in which chlorine was afterwards generated. Oxygen was passed into the chlorine mixture (manganese dioxide and hydrochloric acid), and the mixed gases then led into the closed chamber. 7.6 litres of oxygen and 3.8 litres of chlorine were thus passed slowly in, but the pressure in the vessel only increased to about 20 mm. water. In the experiments with chlorine and oxygen it was always found that better results were obtained when the oxygen was passed into the chlorine-generating mixture than when the gases were simply mixed before reaching, or in, the bleaching chamber. I am, however, unable at present to say whether this was due simply to more intimate mixture of the two gases, or whether possibly small quantities of some oxide of chlorine were produced.

Sufficient experiments have not yet been made to enable me to say with any certainty what is the chemical explanation of the above phenomena. It is conceivable that the oxygen in some way regenerates the chlorine or bleaching powder at the moment of their conversion into hydrochloric acid or calcium chloride, or, on the other hand, that a part of the oxygen becomes converted, in the presence of the nascent chlorine, into ozone. It is more probable, however, that the bleaching of the natural colouring matters present in fibrous materials does not take place at one bound, but by stages, some of the intermediate products being of an aldehydic or unstable character, and oxydisable by free oxygen. Under ordinary circumstances, no free oxygen being present, the end as well as the initial oxidation must be effected by nascent oxygen supplied through the medium of the chlorine. But if a plentiful supply of oxygen is present, less nascent oxygen, and consequently less chlorous bleaching agent, is required. One fact that tends, I think, to confirm this explanation is, that when a current of oxygen is passed through a solution of bleaching powder undergoing titration with arsenious acid, the amount of arsenious acid is not increased. Were the increased bleaching effects described above due to a formation of ozone or a regeneration of oxy-chlorine compounds, an increased quantity of arsenious acid should be oxydised under the conditions just mentioned.

Use of Oxygen in the Purification of Gas.

As Mr. W. A. Valon recently (June 1888) read a paper on this subject at the annual meetings of the Gas Institute, and this paper, with the discussion thereon, has already appeared in the Transactions of the Institute (1888, pp. 71—98), it will be unnecessary for me to go into the question in detail. It is, however, of such importance, that I may be permitted to give a brief summary of the principal results.

In gasworks where oxide of iron is employed for the removal of the sulphur from the gas, the spent oxide is often revived by being exposed for some time to the air, and this may be repeated ten or a dozen times before the oxide is finally spent. But in order to save the handling of the oxide thus made necessary, a small percentage of air is often added to the gas before it enters the oxide purifiers, and in this way the revivification is made continuous, till the oxide is finally completely spent. But when either of these plans is adopted, the purified gas is generally found to have lost somewhat in illuminating effect, due probably to the nitrogen introduced in the added air. Mr. Valon made a series of experiments to ascertain whether any material advantage would accrue by the substitution of a corresponding amount of pure oxygen for air. He found that not only did the loss of luminosity give place to a slight increase, and the revivification of the oxide proceed more regularly, but that the use of the oxide might be abandoned altogether. For when oxygen was employed in this way, the lime purifiers alone were found to efficiently remove the sulphur compounds, the issuing gas containing only 6 to 8 grains of sulphur per 100 cubic feet of gas. The proportion of oxygen found to give the best results was 0.10 per cent. of the volume of the gas for every 100 grains of sulphur per 100 cubic feet of crude gas. Under these conditions the sulphur remained fixed in the lime (partly as free sulphur), and did not move forward when the lime became saturated with carbonic acid—as is the case where air is employed—and the life of the lime was nearly doubled. The lime lasts much longer than hitherto, owing to the more complete revivification of the lime, and when spent, it has not the noxious smell of "blue Billy," but forms an almost odourless and dry substance. The purifying space and plant is reduced by more than one-half, and the labour in proportion.

The chemical explanation of these results must be left for the present unknown, but of the actual facts there is no doubt. The experiments were made at the Westgate-on-Sea Gas Works, between September 1887 and May 1888, and during that time the whole output of gas was treated by the oxygen method. Permanent oxygen plant has now been put down at the Ramsgate Corporation Gas Works, and the process will shortly be at work, when those interested in gas making will be able to examine it personally.

Maturing of Spirits.

Another application of oxygen, which, though not yet fully worked out, promises to be of considerable importance, is its use in the maturing of spirits. There is little doubt that in the early ageing of spirits in cask, the oxygen of the atmosphere plays an important part. But though this is the case, all attempts to artificially hasten this process seem hitherto to have proved more or less unsatisfactory. But the two applications just referred to show that oxygen when in the pure state may sometimes answer where air utterly fails, and this is also the case in the ageing of spirits. It has been found that if oxygen is forced into spirits at a pressure of one or more atmospheres and left for ten days or so, the spirits become mellowed to the extent of about three to five years ageing. Numerous samples have been thus treated and submitted to experts, with the almost invariable result as stated. Determinations of the fusel oil in some of these samples have been made, of which the following three pairs are examples.

Fusel Oil.

I. Whiskey before treatment.....	72	grms. per litre.
Whiskey after treatment	706	" "
II. Whiskey before treatment	73	" "
Whiskey after treatment	702	" "
III. Whiskey (quite new Scotch) before treatment	1763	" "
Whiskey (quite new Scotch) after treatment	742	" "

From these numbers* it is clear that the effect of the oxygen is really to mature and improve the spirit and convert the harmful fusel oil into innocuous compounds. It may be mentioned that oxygen has for some time past been used in France for this purpose.

Some wines appear also to be matured by this process, but they are also often acidified by it, and it is doubtful whether it will be applicable to wines with advantage.

Use of Oxygen for obtaining High Temperatures.

As the able paper delivered by Mr. Thos. Fletcher on this subject to the Liverpool Section of our Society has already appeared in our Journal, it is unnecessary for me to do more than refer to it. I would, however, take this opportunity of calling the attention of chemists who have not yet used it to the convenience of compressed oxygen as now obtainable in steel cylinders, for laboratory use. There is also little doubt that at the prices mentioned at the commencement of this paper, oxygen will be available even in some metallurgical operations where very high and readily controlled temperatures are required.

Several other industrial applications of oxygen are now under investigation, and I hope ere long to have the honour of bringing these before the notice of the Society.

DISCUSSION.

The CHAIRMAN said that he was sure all the members would agree with him in thanking Dr. Thorne for an especially interesting paper. It was surprising that oxygen had been so completely shut out from all industrial uses until recently. The most familiar of all chemical substances, the first thing to a knowledge of the use of which every beginner in chemistry was introduced, had hitherto been so scarce and valuable that its industrial employment was impossible. Excepting a very limited use in oxyhydrogen furnaces, it might be said that the industrial application of oxygen in chemistry was unknown. Messrs. Brin's process had created the possibility of the industrial use of oxygen, and was in itself a most interesting object of study. The first effects of the introduction of this process were a repetition of what had been so often seen before:—a discovery was made so simple and so admirably fitted for its purpose, that everybody immediately concluded that the whole question was solved. Then the practical difficulty of applying the process came to the fore. Perhaps there was nothing more certain with respect to industrial processes than that nothing, however perfectly simple in the laboratory, ever worked well at first on a practical scale. It

* It should be noted that these numbers are given rather for their relative than their absolute value. In these determinations the numbers to be compared are from the *same* spirit before and after treatment, and therefore are in a great measure free from the objections raised against ordinary fusel oil determinations. The alcohol of the spirit was carefully fractionated off by the help of a Le Bel-Henninger fractionating tube (four bulbs), and the aqueous residue treated by Marquardt's method.

was not merely beautiful laboratory experiments that were wanted in applied chemistry, but the more complex results of great engineering and manufacturing experience allied to that purely theoretical chemistry which we are apt to think all-sufficient. It was most interesting to see how the difficulties besetting the process had been overcome, and results obtained indicating that the various applications of oxygen had a great future. The whole question of bleaching was one of great interest and importance, but he would not venture to dogmatise on it. Undoubtedly oxygen had for centuries past done a large amount of bleaching; in fact, until the present generation or thereabouts, all bleaching had been done by it. At any rate, without going deeply into theories, one might assume that oxygen had *some* bleaching power. How that power was exercised was a difficult and interesting question. He felt strongly, however, that Dr. Thorne was right in his view that chlorine was not the true bleaching agent. It was probable that it acted simply as—it was difficult to choose expressions which did not bring one on to debatable ground, but perhaps he might use a safe, if incomprehensible, expression, and say that it acted in a catalytic manner. At any rate it seemed clear that the joint presence of ordinary oxygen and oxygen combined with chlorine did somehow produce the effects characteristic of ozone. If this process could avert the destructive effects produced by chlorine in paper pulp, it would be a vast consideration to all who had respect for the permanence of documents; and if it could be carried still further and avoid the extreme use of chlorine in our clothes, that would be an improvement which would add materially to the happiness of the community. It must be confessed that modern science had not succeeded in producing the same permanence which the linen of our grandmothers showed; and if the oxygen process could restore that permanence, everybody—except those whose business it was to spin—would be grateful. The other proposed applications of oxygen were striking and interesting. In the case of spirits, if we could be saved what had been called forelight processions down our throats, that alone would be a great improvement. The ageing of spirits was another of those simple processes difficult to analyse and work out. Everyone knew that it took place, but no one seemed to know how. It would certainly be an economic and valuable application of oxygen if the interest of large sums of money which at present lay idle while spirits were ageing could be thereby saved. He would not go through all the possible applications of oxygen, some of which were well recognised at present, while others belonged only to the future, but would call upon those having knowledge of the subject—especially those learned in the purification of coal gas—to give the meeting the benefit of their experience.

Mr. S. H. JOHNSON said that with respect to the bleaching properties of oxygen, he would like to ask Dr. Thorne whether he had compared the cost of the oxygen used with that of the chlorine which it displaced. A thousand cubic feet of oxygen would weigh, roughly, about 14 lbs., and its cost would be 7s., or about 6d. per pound. In comparing the cost of that oxygen with that of the chlorine which it displaced, one must take the chlorine in the form of bleaching powder. He thought that the two values would be found to be about equal, and thus there would be no saving. It was, however, very interesting to find that oxygen could be used directly in such a way, and it was to be hoped that the process would be cheapened in the future. He would like to hear

Dr. Thorne's opinion of the saving to be effected by using oxygen instead of oxide of iron for the purification of gas. He had had a long experience of the use of oxide of iron and of lime for that purpose. One of the principal objections to the use of lime was the enormous expense of handling the lime; but this expense was saved in the case of iron oxide by the same oxide being used over and over again, and he had no doubt whatever that oxide of iron was by far the cheaper agent for purifying gas from sulphide of hydrogen.

MR. B. E. R. NEWLANDS asked how it was possible to correctly estimate such a small quantity of fusel oil in spirit as that mentioned as existing after treatment by oxygen. He had failed to get accurate results by the book methods, and therefore when he inquired into the matter during a recent visit to Paris he was somewhat gratified to find that one of the most eminent chemists in the alcohol industry confessed himself equally at a loss to estimate such minute proportions of fusel oil. In fact, fusel oil was a very complex body. It was essentially a mixture left in the still after the alcohol was distilled off at a certain temperature, and the oil at one manufactory might differ considerably from that at another. Therefore a process that would determine it correctly in one works would perhaps fail to determine it at another.

MR. E. J. BEVAN was glad to find that Dr. Thorne regarded oxygen as the chief agent concerned in bleaching rather than chlorine. At the same time he would like to know how Dr. Thorne explained the action of chlorine on jute in the experiment he had described in which he had passed chlorine gas into a glass cylinder containing jute. It was well known that jute was not bleached at all under such conditions. The chlorine was absorbed by the jute, forming a chlorine compound of definite composition, and thus accounting for the non-increase of pressure mentioned by Dr. Thorne. He would like to know, too, whether the bleaching effected by means of oxygen and bleaching powder had been found to be permanent. That was a matter of great importance to paper-makers. It was possible to produce what might be called a white wash as contrasted with a distinct bleach. In some cases bleaching could be effected very rapidly, and a good white apparently obtained; but after some time the pulp rapidly deteriorated and went back to the original colour. But after all, the most important point for a paper-maker's consideration was the relative cost. He would like to hear Dr. Thorne's opinion on that, and also whether he had estimated the loss in weight which occurred with pulps treated by the two different processes—*i.e.*, by bleaching powder alone and by bleaching powder in conjunction with oxygen. He would also be glad to know whether Dr. Thorne had determined what action, if any, was produced by oxygen alone, without the use of any bleaching powder.

DR. C. R. ALDER WRIGHT asked whether the "blue Billy" shown by Dr. Thorne contained free sulphur or calcium sulphide, or whether the sulphur compounds in it had been oxidised to sulphate; and whether the action of the oxygen had been traced by the analytical examination of the product. There was another application of oxygen which had been brought forward some time ago, which Dr. Thorne had not mentioned; that was its use for purifying water by being dissolved therein. It was a curious fact that a watery solution of oxygen under several atmospheres pressure in a syphon when discharged into a tumbler was just as tasteless as boiled water.

Though "fizzing" vigorously it tasted as flat as ditch-water. He had gathered from Mr. Jackson some time ago that there was a prospect of oxygen being used for the purification of water containing organic matter, but had not yet heard of any experiments to that end. Mr. Jackson had, however, kindly sent him for home consumption sundry samples of plain aerated water and of lemonade aerated with oxygen. He had noticed that the oxygen had by no means completely oxidised the citric or tartaric acid of the lemonade nor the essential oil and sugar contained therein, and it therefore occurred to him that there might be certain constituents of ordinary water which it would equally fail to oxidise.

MR. C. T. KINGZETT asked whether Dr. Thorne had made any estimation of the comparative cost of oxygen by the Brin process and in the form of peroxide of hydrogen in the application of the two substances to such bleaching processes as the oxidation of paper pulp and fusel oil. And further, whether the oxygen employed to purify gas prevented the formation of that magnetic oxide of iron which was the bugbear of the process. If one could really prevent the formation of magnetic oxide there was no reason why the ferric oxide should not be employed *ad infinitum*.

MR. A. WINGHAM said he understood that the sulphur in the "blue Billy," shown by Dr. Thorne, was in the state of free sulphur. If that was so, it seemed very remarkable that one should introduce oxygen into the gas and get a reduction. The probable explanation seemed to him to be that the oxygen being introduced into the gas burnt by preference a certain amount of sulphuretted hydrogen into sulphurous acid, which, reacting on the unburnt sulphuretted hydrogen, gave free sulphur; the lime acting simply as a mechanical filter. If that was so, the objection to the cost of lime would be overcome, as coke could be used. With respect to the application of oxygen to bleaching, he would like to ask Dr. Thorne to what extent he could replace chlorine by oxygen; and, if the oxygen had a catalytic action, whether he had experimented as to the amount of chlorine necessary to enable oxygen to bleach, whether a trace only would be sufficient. In this connexion he would draw attention to the great desire that existed at the present time for a really pure paper for artistic purposes. He had had complaints recently from several artists that the paper supplied to them rapidly destroyed the colours put on them, especially the vegetable colours. There would certainly be a demand for any process which should overcome this fault.

MR. H. SHARP said that he was glad that, though a member of the Society, it did not fall to his lot to answer the various technical questions raised on the subject of Dr. Thorne's paper. One gentleman had inquired as to the cost of bleaching by oxygen as compared with peroxide of hydrogen. Dr. Thorne would probably answer that question; but in the meantime he might say that they had not attempted to compete with peroxide of hydrogen—or rather that hydrogen peroxide had not, he thought, attempted to compete with their oxygen. The former would, he believed, be much more expensive. His object in rising, however, was, as chairman of Brin's Oxygen Company, to emphasise an invitation which had already been sent to the Council. He trusted that the Council would accept that invitation, and that the Society, on its annual meeting this year in London, would pay a visit to the works

and see the industrial production of oxygen going on. It was unfortunately beyond their power to show members all the applications of oxygen; but he would assure them of a most hearty welcome. He would now leave the answering of the questions to Dr. Thorne.

Dr. THORNE, in replying, said: In the first place as to the question asked by Mr. Johnson, and repeated by other gentlemen, concerning the relative cost of oxygen and bleaching powder— if Mr. Johnson reflects for a moment he will recognise that he has made a slip in his calculation. A thousand cubic feet of oxygen weigh about 81 lbs., and not 14 lbs. as he mentioned—the volume of one pound of oxygen at the ordinary temperature of 60° Fah. being about 11·8 ft. This, of course, will reduce the cost of the oxygen from the sixpence suggested by Mr. Johnson down to about a penny per pound. I may say, however, that we have studied the question of the cost of bleaching, and it would be within the mark to say that the ordinary cost of bleaching paper pulp is about 15s. to 18s. per ton of raw material. In some cases it is a little higher, in others a trifle lower. As already mentioned in my paper, in experiments on the large scale a saving was effected of about 30 per cent. of this cost, which is equivalent to between 5s. and 6s. That saving has been effected at the cost of from 180 to 250 cubic feet—or an average of about 200 cubic feet—of oxygen to the ton of raw material. This quantity of oxygen costs in London about 1s. 6d., and we, therefore, have to deduct that sum from the saving of 5s. or 6s. In the midland and northern counties, where coal is cheaper, the cost of the same quantity of oxygen would be about 1s., so that on the lowest estimate of 30 per cent. less bleaching powder used there would be a clear saving of 3s. or 4s. I am confident, however, that in fitting up a complete apparatus a greater economy—say 40 per cent.—could be effected, which would of course proportionately increase the money saving. I may mention that at a large mill where the experiments were made, and where about 150 tons of esparto are treated per week, the proprietors are so satisfied with the results obtained with the 50 tons experimented on that they are on the point of putting up plant. It is now only a matter of settling the details of agreements as to terms. With respect to the question of gas purification, there are a good many points at which a saving may be effected. In the first place we may do away entirely with the oxide of iron. The saving in cost of oxide will be small, but the saving in space, handling, and so on, is by no means small. We shall also be able to reduce even then the amount of lime used, and the space for the lime, which is very considerable, by nearly one-half. Consequently there will be a further saving on the handling of lime. Then there will be another and appreciable saving in obtaining an increase of luminosity instead of a decrease in the purified gas. In the ordinary gas where air is used for the revivification of the oxide of iron, the gas almost always loses a certain amount of luminosity. It may be only half a candle or less, but it does lose. Where oxygen is used there is an undoubted increase of about half a candle-power. This increase is no doubt due to a trace of oxygen left in the gas, which is not sufficient (the total quantity used being very small—only about 6 feet per 1,000 feet of gas) to appreciably increase the rate of consumption of the solid particles of carbon in the flame, but is yet sufficient to increase its heat, and thus increases the luminosity. Referring to Mr. Newlands' remarks, I appreciate the difficulty

of the fusel oil determinations, and shall be as glad as he will be to find a satisfactory method of analysis. But in this instance I do not have to contend with the same difficulty as the ordinary analyst. I should be sorry to say that the '28 which I have written down is an accurate determination of the fusel oil. But I have the great advantage in this case that I am comparing the *same* spirit before and after treatment. I have not to deal with one fusel oil made in one distillery and another made elsewhere. The value of my results is relative rather than absolute, the same spirit having been analysed in the same way before and after treatment by oxygen. The method used was a modification of the Marquardt method. Most of the alcohol and part of the water was carefully distilled off in a Le Bel-Henninger fractionating apparatus. When the temperature has risen to 93° or 95° C the residue (which is almost free from ethyl alcohol) was treated by the ordinary extraction method with chloroform, oxidised with bichromate of potash and sulphuric acid, and the fatty acids produced were estimated in the ordinary way. Referring to Mr. Bevan's remarks as to the action of the chlorine on jute, I may say that to avoid carrying my paper into great detail I omitted one thing which might have been stated with regard to these experiments. The action of the chlorine on the jute was not a complete bleaching action. In all cases, after treatment with chlorine, the jute required to be finished off with a dilute solution of bleaching powder. When the jutes came out of the chlorine chamber they were more or less orange-coloured, but they were so far acted on as to require very little finishing; and in my results, where comparison is made between jutes bleached with oxygen and chlorine, and those where no oxygen was used, I was careful to keep the finishing solutions very dilute, and equal in quantity and strength. I quote that example as showing the absolute absorption of a very large quantity of oxygen during the bleaching process. In answer to the question as to the permanence of the whiteness, I may say that, as far as can be judged, in all cases the oxygen-bleached materials stand better than those bleached with chlorine or bleaching powder. In the case of the jute bleachings this was very marked. We had samples bleached equally by the two methods. They were equal in colour at the end of the experiment; at the end of four days the oxygen-bleached one retained its whiteness much more completely than the other. This was also the case when working on the large scale, and was noticed by the workmen. When they get their wet pulp bleached on a Saturday night and it has to stand till Monday morning, they generally find it "go back" a little. One batch of oxygen-bleached pulp stood in that way, and the men remarked that it had not "gone back" at all. The question of loss of weight has been tested, and in all cases where oxygen has been used in conjunction with bleaching powder or chlorine the loss of weight has been considerably less—sometimes 50 per cent. less—than in the corresponding cases where chlorine or bleaching powder alone was used. Mr. Bevan asked if I had made experiments as to the action of oxygen alone. I have made a great number of such experiments—at high and low pressures, and at high and low temperatures. In some instances there seemed to be a very slight bleaching action, but in the majority of cases no change could be detected. I may say, therefore, that under ordinary conditions of simple mixture with or exposure to oxygen, I have as yet been unable to produce any change, unless a temperature

was used too high for practical purposes and likely to damage the goods. Referring to the spent lime in gas purification, the sulphur is present partly as reduced sulphur, partly as sulphide, partly as sulphate, and partly also as sulphite. The relative proportions appear to vary, but the actual ratios between them have not been much studied as yet. As far as can be judged, about a quarter to one-half the sulphur is always in the free state, the remainder being in combination. Mr. Sharp has referred to the relative cost of oxygen and hydrogen peroxide, and I can only add that the cost of hydrogen peroxide is so high at present that it can only be used for special purposes, such as the bleaching of ivory, where the action of such agents as chlorine would be detrimental, and where the users can stand the high cost. Could we obtain hydrogen peroxide in a more direct way and at a lower price, no doubt there would be a great field for its powers as a bleaching agent. With regard to the action of oxygen on oxide of iron, converting it into magnetic oxide, I cannot give any information, our experiments having been directed in the first instance only to testing whether the increased action due to the oxygen was sufficient to make it worth using. We soon found that we were able to get rid of the oxide of iron, and our work after that turned exclusively to the examination of the purification by lime, and the products of the action of the oxygen have received but little attention as yet. Dr. Wright asked about the action of oxygen on water. As far as the Oxygen Company is concerned, we have never claimed the purification of ordinary potable water by compressed oxygen. I do not believe that oxygen will have by itself any appreciable effect in purifying potable water. It may, either alone or in conjunction with other materials, be used at some future time for the purification of sewage and similar matters where the organic matter present is of a less stable character; but for improving a potable water containing only the ordinary contaminations there appears no likelihood of its having any value. With regard to the replacement of chlorine by oxygen, my experiments have shown that as we increase the proportion of oxygen to chlorine or bleaching powder, we improve the bleaching effect up to a certain point. When that point is passed the effect remains stationary for some time and then begins to decrease. In the case of chlorine and oxygen, an increase of effect has been noticed up to about two volumes of oxygen to one of chlorine. Up to three or four volumes of oxygen there is very little difference; but if we increase the proportion of oxygen beyond that, we get a loss of bleaching effect. I fear I cannot give Mr. Wingham much hope of a purer paper. No doubt where the use of chlorine or bleaching powder is reduced the paper is increased in purity and tensile strength. Whether or not the bad effects he has mentioned are due to chlorine remaining in the paper I cannot say; nor can I say whether they would be removed by the use of oxygen. It is probable, however, that the use of oxygen would produce an improvement in that direction, because the less chlorine there is used, the less action is there on the fibre of the paper.

Mr. S. H. JOHNSON accepted Dr. Thorne's correction of his mental calculation, but said that another point had since occurred on which he thought he would not be wrong. The oxide of iron used by the gas companies hitherto really cost them nothing, because they got more for their spent oxide than they paid for it originally. At any rate the vendors of it were willing until recently to supply it to the gas

companies free, provided they received back the spent oxide.

Dr. THORNE: With reference to that point, I have already stated that we base our hopes of saving largely on the economy in handling. It is very exceptional, I think, that the gas companies actually get more for their spent oxide than they give.

Mr. JOHNSON: They always do.

Dr. THORNE: I understood that usually a small rental was paid by the gas companies. But even if they do receive slightly more, we shall be able, I think, when we get to work, to show an ample margin for saving.

MR. E. MELLOR IN THE CHAIR.

ON THE ESTIMATION OF CHLORINE AND HYDROCHLORIC ACID IN A MIXTURE OF THE TWO GASES.

BY WILLIAM YOUNGER.

DIFFICULTY has been experienced in detecting and estimating hydrochloric acid in small quantity in the presence of chlorine in a mixture of these two gases.

It is necessary to deal with this mixture in the gases from the ordinary chlorine still, and more especially in the gases from the Deacon process.

One method employed for this purpose consists in passing the gases through a solution of caustic soda. In this method it is assumed that all the free chlorine is converted into hypochlorite, and that no chloride is formed. This, however, is fallacious, and where there exists very small quantities of hydrochloric acid in the gases it is impossible to obtain any reliable results.

Another method is that in which water is used as an absorbent, the free chlorine being eliminated by means of mercury; but this method I have found unsatisfactory, as the impurities in the mercury vitiate the results, even when the purest mercury which I could purchase was employed.

The method which I find to give very accurate results is by absorbing the gases in a solution of arsenious acid.

The absorption is accomplished in one vessel, which, along with a graduated box as an aspirator,

enables us to get a direct reading of the grains chlorine per cubic foot; while from the same solution, by titration with silver nitrate, we obtain the hydrochloric acid, if any be present in the gases. This is done as follows:—

In the accompanying figure a glass tube A, 20 inches long by seven-eighths of an inch in diameter, is employed for absorbing the gases. This tube is fitted up with other two tubes. Over the bottom end of the long tube is tied a piece of thin cotton cloth, which serves to break up the gas bubbles as they emanate from the lower end of this tube. Two pieces of copper wire are also twisted round the lower end of the long tube, the four ends of which are allowed to project for the purpose, of keeping it in the middle of the absorbing tube, and thus prevent the gas bubbles from travelling up the side. Wire was used for this purpose, so as to cause as little obstruction as possible to the passage of the gases up the tube, and thus prevent the gas bubbles from coalescing.

Into this tube are put 100 cc. of a standard solution of arsenious acid in water, every cc. of which equals 0.15432 of a grain chlorine, so that the 100 cc. equals 15.432 grains, and to which is also added from the end of a glass rod a very small portion of sulphate of indigo paste, which serves to indicate when the aspiration is finished.

The 100 cc. gives a column in the tube of 10½ ins., in which the gases are completely absorbed.

Behind this tube is placed a bottle B, containing solution of iodide of potassium (a gramme or so dissolved in water), which also serves as an indicator, and this bottle in turn is coupled up to a graduated box C, fitted up as an aspirator. A cubic foot in capacity of the box is divided out into as many parts as desired; in our own case I have divided it out into 112 parts.

This aspirator is provided with a gauge-glass D, down the one side of which are the readings for the grains chlorine per cubic foot, while down the other side on the same lines are the number of cc. drawn through, the latter being required in order to obtain the grains hydrochloric acid.

In taking an aspiration the indication appears first in the iodide of potassium bottle by the liberation of iodine, and shortly afterwards the sulphate of indigo in the tube becomes bleached, when the aspiration is stopped and the readings taken from the diagram.

Supposing the line marked E to represent one cubic foot, and supposing the aspiration to be finished when the level of the water in the gauge-glass stood at this line, then the grains chlorine per cubic foot would be exactly 15.432, supposing it to be finished when half a cubic foot had been drawn through, then it would indicate twice that quantity, and so on, doubling itself every time the quantity drawn through is halved. The figures for the intervening readings must, however, be calculated, as starting from the bottom upwards the increase each time is not a fixed number, but a constantly increasing number.

From the same aspiration is also obtained the grains hydrochloric acid per cubic foot, as follows:—After taking an aspiration, 10 cc. of the solution from the tube are titrated with decinormal silver. Supposing no hydrochloric acid to be present in the gases, then 28.2 cc. of silver will be required, being equal to the hydrochloric acid produced by the oxidation of the arsenious acid. Any silver solution required beyond 28.2 cc. is due to hydrochloric acid in the gases, which is calculated into grains per cubic foot by reading off the number of cc. drawn through.

If the experiment be carried out with ordinary care, and the aspiration be stopped just when the colour of the sulphate of indigo is discharged, it will be found that a portion of the solution out of the tube will neither take up any iodine nor discharge the colour of sulphate of indigo, showing that the arsenious acid has all been oxidised, and that no free chlorine is present; or, in other words, that it has neither been overdone nor underdone.

The iodine liberated in the iodide of potassium bottle generally indicates about 0.2 or 0.3 of a grain, and sometimes as low as 0.1 of a grain chlorine.

When two iodide of potassium bottles are put on, it is never found that any liberation of iodine takes place in the second bottle, thus showing that no chlorine escapes beyond the first bottle.

The iodide of potassium is not necessary as an indicator, as a clear indication is always obtained by the sulphate of indigo in the tube. One purpose the iodide of potassium bottle serves is to indicate if the aspiration be running too quickly, for if so, then a little of the chlorine will escape absorption in the tube, but that will not happen if it be kept running at an ordinary speed.

In order to ascertain if any hydrochloric acid escaped absorption in the tube, a bottle containing water was put on behind the tube, in place of the bottle containing iodide of potassium, and the aspiration stopped just immediately before the oxidation of the arsenious acid was complete, so as to avoid the slight trace of chlorine which escapes absorption in the tube at the finish.

On titrating the contents of this bottle with silver solution, no hydrochloric acid was found, thus showing that no hydrochloric acid had escaped absorption in the tube. If a bottle containing silver solution in place of water be employed, a similar result is obtained.

These experiments have been repeated a number of times with similar results.

A method by which a constant aspiration over the 24 hours for the hydrochloric acid in the Deacon gases is obtained as follows:—

In working the Deacon process a constant aspiration over the 24 hours is taken for the grains chlorine, the gases being absorbed in two bottles containing solution of caustic soda, a Bunsen pump and a meter being also employed.

A Winchester quart containing two litres of distilled water is placed in front of the two bottles containing

caustic soda. The hydrochloric acid is absorbed by the water in this bottle, along with part of the chlorine, the remainder of the chlorine being taken up by the caustic soda in the other two bottles.

The water and the caustic soda solution are each titrated separately for the chlorine, and calculated to grains per cubic foot.

Air is then blown through a portion of the water until all the free chlorine is eliminated. Whatever hydrochloric acid may have been present is left in the water, a measured portion of which is then titrated with silver nitrate, and the grains hydrochloric acid per cubic foot calculated. During the blowing evaporation takes place, but no loss of hydrochloric acid is sustained, as it has been proved by experiment that where very small quantities of hydrochloric acid exist, as in this case, that the hydrochloric acid increases just in the same proportion as the bulk of the solution decreases.

As the blowing takes up a considerable time, I have had an arrangement fitted up to the fan blast in the blacksmith's shop, under lock and key, where the blowing can be continued any length of time.

YORKSHIRE GREASE.

BY GEORGE H. HURST, F.C.S.

IN our technical literature but few references are to be found on this subject, and even these of a limited scope.

I propose to deal with the subject under two heads:—

1. Yorkshire grease: its origin, composition, and the products obtained from it.

2. The composition and properties of these products.

Yorkshire Grease: its Origin, &c.

In the woollen industry a large quantity of soap and oil is used in cleansing, milling, and oiling the fibre, yarn, and cloth, during the different processes involved in spinning and weaving wool. Formerly all these products, or rather the waste from them, went into the rivers in the form of soapsuds, and thus helped to pollute them.

Now, almost the whole of the soapsuds of the woollen mills of Yorkshire and other districts is treated with acid and the fat liberated used again for making soap.

The soapsuds are collected into a large tank, calculated to hold a day's supply, say from 6,000 to 8,000 gallons of liquor. Usually two tanks, constructed of brickwork or concrete, are provided, one being used to collect the suds, while the suds collected in the other tank are being treated in the manner following.

Brown oil of vitriol, or, preferably, hydrochloric acid, is added to the suds, and after thoroughly agitating the mixture it is allowed to settle; the fatty matter comes to the top, is skimmed off, and thrown on to large cloth filters to drain. The fatty matter thus collected is known as "magma" or "sake," and the operation of treating the suds with acid is commonly known as "saking," probably a local corruption for "seeking."

This "magma" is then sent to the grease mills, while the residual liquid is run into the rivers.

The "magma" is now put into bags, which are piled up in a tank and weighted, and so left for a

night, when a large quantity of water is pressed out. Then the cakes of magma are placed in a hydraulic filter-press kept hot by means of steam, and subjected to pressure, when a dark greasy product is pressed out, and a more solid matter is left behind in the bags. The latter is known as "sud cake," and is used as manure.

The greasy matter referred to is known as "YORKSHIRE GREASE," of which I have a few samples here.

This body is sometimes used for making soap for wool scouring, but is more frequently distilled, as will be described later on.

Yorkshire grease varies a little in appearance, but usually is of various shades of brown, sometimes almost black. It is very sticky, and easily melts, its melting point being 44° C. On treatment with soda or potash it undergoes saponification; the soap so produced is not readily soluble in water, and is of very short grain. Its specific gravity at 15.5° C. varies from 0.939 to 0.957. So far as my experiments go the lower specific gravity is always associated with a low percentage of unsaponifiable matter.

It contains free fatty acids, unsaponifiable matter, and neutral oils, &c. The free fatty acids vary with different samples according to the character of soap or fat originally used; the unsaponifiable matter contains cholesterol, derived from the natural fat of the wool, and probably also some of the mineral oil which has been used in the wool batching. It also contains water and mineral matter.

The following table shows the composition of four samples of Yorkshire grease:—

	1.	2.	3.	4.
Sp. gr. at 15.5° C.	0.9391	0.9417	..	0.9570
" " 28° C.	0.8900	0.8952	..	0.8720
	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Water	0.798	1.53	1.21	0.94
Fatty acid	18.61	24.25	24.15	26.43
Neutral oil	68.62	58.25	50.02	16.86
Unsaponifiable oil	11.68	15.83	44.44	55.77
Ash	0.11	0.14	0.18	Trace.
	100.00	100.00	100.00	100.00

The fat is also used in the manufacture of lubricating greases, and it may be of interest to give its flashing point, &c.:—

	° C.	° F.
Vapourising temperature	182	359
Flashing point	220	428
Fire test	248	478

I have already mentioned that Yorkshire grease is subjected to distillation, which process I will now briefly describe.

The process of distillation is carried on in cast-iron stills (wrought iron cannot be used as it is rapidly corroded by the fatty acids), similar in shape to tar stills, and which are connected with suitable condensing arrangements.

In most works superheated steam is used along with direct heat, its use giving a larger yield of useful products and of better quality than when direct heat is used alone.

The stills are of about 1,000 gallons capacity, and will hold something like four tons of grease. When beginning the distillation, direct heat is used alone until the water in the grease has been driven off,

which will take from 10 to 16 hours, after which superheated steam is run in and kept running into the still during the rest of the time.

Some kinds of grease give off a small quantity of a light "spirit oil;" others do not yield this product. After this comes the principal product, a thin limpid oil of a pale yellow colour, which, on cooling, sets into a pale yellow grease known as "first distilled grease." This grease takes from 20 to 24 hours to come off; it is followed by a greenish oil which is collected separately and is known as "green oil" or "crude grease;" this product is usually put back into the stills with a fresh quantity of grease, or occasionally made into very crude lubricating greases.

After about 36 hours from the beginning of the distillation a thick oil begins to appear. When this occurs, the fires are drawn, and the "pitch" which is left in the still is drawn off.

The products yielded by the first distillation of Yorkshire grease are given in this table:—

	Per Cent.
Water and loss.....	20.76
Spirit oil.....	4.10
First distilled grease.....	45.54
Green oil.....	15.47
Pitch.....	14.13
	100.00

The "first distilled grease" may be treated in two ways: (a) it may be again distilled; or (b) subjected to pressure, thus yielding two products, oleine and stearine.

(a) The "first distilled grease," obtained as described in the first distillation, is now put again into the stills and treated as before, when two products are obtained, "second distilled grease" and "pitch." The latter is softer than that obtained in the previous distillation, and is hence termed "soft pitch." The principal object of this second distillation is to obtain products of a better quality and purer colour.

The "first distilled grease" yields about 96 per cent. of "second distilled grease," and 4 per cent. of pitch.

The "distilled greases" obtained during the first and second distillations are collected in a tank, and allowed to cool slowly, and kept at a temperature of 21° C. for some hours; by this means the stearine it contains separates out in a granular form, which facilitates the after process of pressing. A great deal depends upon the careful cooling of this grease to obtain the maximum yield of oleine with the minimum amount of damage to the press cloths. This operation of "seeding" is sometimes done in shallow metal trays, placed on racks in a slightly inclined position, the racks being in a room kept at from 21° C. to 25° C. The oleine which drains out of the stearine is generally considered to be of better quality than that obtained by pressure, and is designated No. 1 oil. The principal objection to this process is the rapid corrosion of the metal trays, while the metal dissolved in the oleine causes the discolouration of the latter.

The cooled "grease" is now put into canvas cloths, and made into cakes, which are put between the plates of a hydraulic press, where they are subjected to a pressure of about three tons to the square inch for six hours. The liquid oleine No. 2 is thus pressed out, the stearine being left behind in a solid cake.

The grease yields about 66 per cent. of oleine and 34 per cent. of stearine.

The oleine is turbid as it issues from the press, and is clarified by filtering.

The Composition and Properties of Yorkshire Grease Products.

The "spirit oil" as first obtained from the stills is pale yellow, but on keeping at the works generally becomes in time of a reddish-brown colour. The cause of this I will discuss presently.

It has a rather unpleasant empyreumatic odour, and is readily inflammable.

Its specific gravity at 15.5° C. is 0.794. It begins to boil at 150° C., 10 per cent. comes over under 170° C., then it distils regularly up to 240° C., when about 62 per cent. has come over, the distillation then gradually decreases in speed until about 320° C., when about 88 per cent. has come over; the temperature then rises rapidly.

It contains a small amount of free acid, equal to 1.2 per cent. of oleic acid.

Nitric acid acts only slightly on it, sulphuric acid chars it a little, while alkalis simply neutralise the small quantity of free acid it contains.

The distilled greases are of a pale yellow colour, and are granular in structure. Two samples which I have examined had the following composition:—

	First Distilled Grease.	Second Distilled Grease.
Water.....	0.98	1.04
Free acid.....	63.12	66.56
Unsaponifiable matter.....	12.88	13.21
Neutral oil, &c.....	23.02	19.16
	100.00	100.00

It is interesting to note that the second distilled grease contains more free acid and unsaponifiable matter than the first distilled grease. This might be expected, since the distillation of grease must result in partial decomposition of the neutral oils it contains, leading to the formation of acid bodies and hydrocarbons. This is also shown in the analyses of the wool oils given below.

Oleine.—This, which is better known as "wool oil," comes from the press as a pale coloured body, but gradually assumes a pale brown colour. This colouration is undoubtedly brought about by the presence of iron in the oil derived from the press or from the tanks in which it is kept.

These oils are mostly used for oiling wool, hence their name; but they have been used for making lubricating greases and soap.

It varies very much in its composition, even from the same maker, which depends very greatly on the composition of the grease from which it is prepared.

The following table gives some analyses of several samples of wool oil:—

	1.	2.	3.	4.	5.
Sp. gr. at 15.5° C.	0.9031	0.898	0.905	0.900	0.9091
" " 98° C.	0.852	0.8403	0.849	0.8434	..
	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Water.....	1.12	2.33	1.38	2.51	..
Free acid.....	55.02	56.26	53.65	59.83	64.12
Unsaponifiable oil.....	34.66	29.46	16.32	38.92	9.95
Neutral.....	9.20	11.95	28.65	..	25.63
	100.00	100.00	100.00	101.26	100.00

These figures can only be taken as approximate.

The acid is calculated as oleic acid, while probably there are other acids present, both of higher and lower molecular weight.

The flashing points of the two classes of oil differ by about 16° F.:—

	Oil No. 1.	Oil No. 2.	Oil No. 3.
	F.	F.	F.
Vapourising temperature	212	263	172.5
Flashing point.....	338	342	322
Fire test.....	386	379.5	356

It would be advisable to reject any oil that has a lower flashing point than 330° F. for oiling wool.

Stearine.—This product is a hard, pale yellow, solid body of a greasy appearance. That obtained from first distilled grease is of a darker colour than that from second distilled grease, but usually has a slightly higher melting point, and contains less fatty acids and more oil.

The following table gives the analyses of three samples of stearine:—

	No. 1 Second Distilled.	No. 2 First Distilled.	No. 3.
Sp. gr. at 15.5° C.	0.9393	0.9044	..
" " 98° C.	0.836
	Per Cent.	Per Cent.	Per Cent.
Water	0.6	1.48	2.85
Free acid	85.6	76.3	72.13
Unsaponifiable oil.....	0.49	0.4	3.12
Neutral oil	2.11	7.7	..
Solidifying point	45° C., 113° F.	53.5° C., 128° F.	..
Melting point	48° C., 118° F.	57° C., 134° F.	..

The acid was calculated as stearic acid, but I am of opinion that there are acids of higher combining values present. The neutral oil given above was extracted by petroleum ether after neutralising with alkali. There is evidently some other constituent beside those enumerated.

Stearine, when saponified with soda, gives a soap which forms an exceedingly gelatinous mass with water, and from which it is exceedingly difficult to extract with ether any free oil which may be present. It is possible to mix 25 per cent. of paraffin scale with stearine, and yet, on saponification, no separation of mineral oil will be noticed. It is this circumstance which makes wool grease stearine of so much value in making sizing tallow, which are mostly mixtures of paraffin scale and stearine. On the other hand, this gelatinising property of stearine being probably due to the comparative insolubility of the soap it produces in water, makes it a bad article for soap making, and soap made from this stearine is noted as not making much lather.

The pitch is used for various purposes, making waterproof paper, cloth, &c.

DISCUSSION.

Mr. H. GRIMSHAW wished to ask Mr. Hurst about how much of the unsaponifiable oil in the samples of oleine did he attribute to the mineral oil originally present in the oils used for greasing the wool, and about how much did he consider to be unsaponifiable oils produced in the distillation of the grease, as he had always considered in his analysis that the presence of unsaponifiable oils were due to both of these causes. He also suggested that Mr. Hurst had omitted to mention that one of the uses of Yorkshire grease is in the manufacture of lubricants for machinery, the axles of which become overheated, such as those of the tinplate rolling machines, and therefore require a grease which is adhesive and does not melt very easily, and is retained upon the bearings.

Mr. ROWLAND WILLIAMS wished to know what method Mr. Hurst had adopted in the examination of his samples. Some time ago he was engaged at a calico-printing works where they extracted the fatty matter from waste soap, by decomposing it with hydrochloric acid and passing the magma through a hot filter-press. It was afterwards packed in casks and sold to a firm of soap makers on analysis. The method mutually agreed upon was to take a weighed quantity and dry it in the ordinary way, and then to extract the fatty acids with strong boiling alcohol and filtering through a weighed filter. The residue on the filter was weighed, and the fat usually taken by difference. In the case he referred to the recovered grease consisted principally of fatty acids, without any unsaponifiable matter.

Mr. J. CARTER BELL asked what kind of apparatus Mr. Hurst used for determining the specific gravity of grease at 100° C., and also how the "oleine" of commerce was defined, as its composition was a matter of great importance, seeing that some insurance companies would not allow any oil to be used, except oleines, olive oil, and Gallipoli.

Mr. LAKE: Has Mr. Hurst ever heard of damage being done to goods by the Yorkshire grease used in the sizing process? He knew of an instance where a heavy claim was made for some warps, which were supposed to have been seriously damaged, the use of this oil making them very streaky.

Mr. C. RAWSON, of Bradford, said that he could not understand the presence of hydrocarbon oils in normal Yorkshire grease. At all the wool-washing establishments in Bradford and neighbourhood, the raw wool, after sorting, was taken direct to the scouring machines and treated with either a solution of soap alone, or a mixture of soap and an alkaline carbonate. The decomposition of the waste suds was usually effected in a series of large wooden cisterns, which in some cases were heated by steam in order to accelerate the separation of the fatty magma. The grease obtained from the hot presses had still to undergo a further operation, viz., its purification. This was effected by boiling it for some time with dilute sulphuric acid. Yorkshire grease varied very greatly in composition, depending to a great extent upon the quality of the wool from which it had been obtained. In the case of very greasy wool, the recovered grease contained a correspondingly higher percentage of unsaponifiable matter and lower percentage of free fatty acids than the average qualities.

Mr. SINGER asked if Mr. Hurst could say whether the iron in the mineral oils would have any effect on the colour in the process of dyeing the wools. As regards the purification of grease from sand, &c., he thought it would be easy to eliminate any particles that might be mixed up with the grease by dissolving it in bisulphide of carbon or other solvent, and filtering the solution.

Mr. HURST, in reply to Mr. Grimshaw, said the unsaponifiable oil in the samples was not due to the mineral oil in all cases, but was probably due to a small percentage of the fatty acids being decomposed in the process of distillation from the grease, although mineral oils were used for wool oils and necessarily found their way into the grease. It was difficult to distinguish between mineral oil, which had been added in these wool oils, and the unsaponifiable oil naturally present. In reply to Mr. Hart, the term "neutral" oil, as described in the paper, had reference only to saponifiable oils free from acidity. In reply to Mr. Williams, the method of analysis adopted in the examination of the samples was to titrate for the fatty acids, then saponify with caustic soda, and extract the unsaponifiable oil with petroleum spirit. In reply to Mr. Bell, the specific gravity was determined at 98° C. by the Westphal balance. With regard to the term "oleine" as used in commerce, it was very difficult to define. The calico printers' oleine was essentially a distinct product from the candle makers' oleine, or from the Yorkshire grease oleine. The oleine used by calico printers is a liquid oil prepared from castor oil by treatment with sulphuric acid and alkali. The candle makers' oleine is either oleine chemically speaking, or a somewhat impure oleic acid, according to whether it has been prepared by pressure or distillation from fats; and Yorkshire grease oleine is different from either of these. In reply to Mr. Lake, he had not come across any of the complaints mentioned by him with regard to the damage done by the grease in the sizing of cloth, but still he thought it would be quite possible to occur, owing rather to the impure character of the Yorkshire grease stearines. In reply to Mr. Singer, with regard to the effect of iron in the dyeing of wools, he did not think the very minute quantity which was present would have any material effect in the process. With regard to his question as to the use of solvents in the abstraction of grease, he did not think they had been used in this country. In reply to Mr. Rawson, his reply to Mr. Grimshaw would be sufficient to answer his question with regard to the presence of hydrocarbon oil in the grease. In answer to the Chairman, the oil is applied to the wool by means of machines and not necessarily by sprinklers, and he was inclined to think that the blue flame was due to the use of an oil with a low flash point, and that there was a certain quantity of electricity produced by the working of the machine which caused the vapour of the oil to flash. He had known of similar cases in other industries where volatile oils had been used in connexion with machinery. In reply to Mr. Bell, the No. 3 oil in which this flashing was noticed had a flash point of 322° F.

Mr. C. RAWSON: The usual methods of estimating unsaponifiable matters in oils when applied to Yorkshire grease do not give satisfactory results. I have adopted the following plan, which, although somewhat lengthy, is perfectly reliable. A given weight of the sample (4–5 grms.) is saponified in the usual way with an excess of alcoholic potash. The solution is evaporated to dryness, adding when nearly dry a little bicarbonate of soda and some sand or ground

glass. The mixture is then transferred to a Soxhlet's apparatus and extracted with ether. The ethereal solution, which contains all the unsaponifiable matters (cholesterin, &c.) with a little soap, is shaken up with water containing a little potash in a separator. The two liquids now quickly separate, as in the case of a mixture of fatty and mineral oils, and the ether solution is washed with water and treated in the usual way.

Meeting held February 5th, 1889.

DR. G. H. BAILEY IN THE CHAIR.

BISULPHIDE OF CARBON. ITS MANUFACTURE AND PURIFICATION.

BY IGNATIUS SINGER.

BISULPHIDE of carbon is prepared by passing sulphur vapours over red-hot charcoal in a closed vessel; the sulphur combines at this high temperature with the carbon, and CS₂ distils over, which may be condensed. The combination of the two elements being direct, and the reaction of the simplest kind, its preparation would seem to be very easy. Nevertheless many difficulties attend its manufacture—chiefly on account of its great inflammability and the poisonous nature of its vapours—which, however, are purely technical, and will therefore command most of our attention.

On a small scale it may be prepared by heating fragments of charcoal in a porcelain or iron tube to redness, and passing sulphur vapours through it. This is both a tedious and a dangerous way and never employed at present, as CS₂ is now made on a very large scale. Vertical iron or earthenware retorts, about 6 feet high and 22 by 12 inches internal diameter, are now used, capable of making from 4 to 5 cwts. per 24 hours. Great care is necessary to prevent all access of air into the apparatus, as bisulphide of carbon vapour mixed with oxygen or air forms a powerful explosive, which in itself often disastrous, is still further aggravated by the creation of two poisonous gases, thus:—

leaving the nitrogen as a third irrespirable gas. From this it will be seen that the greatest care is necessary to make all joints perfectly air-tight, and above all to exclude air from the generating retort, as no bisulphide is formed while oxygen is present, the sulphur having a greater affinity for this than for carbon. But this was at first by no means an easy matter, as the retort must have several openings for introduction of sulphur and charcoal—the former every few minutes—for the delivery of the vapours and the withdrawal of the ashes; while the necessarily high temperature makes it difficult to find a suitable cement to ensure tightness.

Another difficulty—and perhaps the greatest of all—is occasioned by the large quantity of uncom-

bined sulphur which distils over, and has a tendency to choke up the exit pipes and condensers. Hence every few days the apparatus has to be opened to remove this accumulated sulphur, an operation not at all free from danger, unless proper arrangements have been made to facilitate this part of the work.

From these preliminaries it will be easy to gather what should be the leading features of a good bisulphide of carbon apparatus, and may be summarised as follows:—

1. Absolutely air-tight joints throughout the apparatus.

2. Easy introduction of the sulphur, without admission of air.

3. Easy access to all parts for the purpose of removing sulphur.

4. The charging in of carbon should be quick, and while cleaning out the apparatus the condensing part should admit of being isolated from the retort to prevent sparks entering from the latter into the former.

These points will be more fully explained as I proceed to describe the modes generally employed.

The first to manufacture CS_2 on a commercial scale was Peroncel, in France, about 40 years ago. This apparatus being the oldest is necessarily the most imperfect. It is shown in Fig. 1. I have purposely selected this as one of my illustrations, since in noticing its defects it will afford us good opportunity to study what to do and what to avoid in the erection of a good plant.

The illustration is taken from Richardson and Watts' Technology, where the following description of it is given:—

"A is a metal cylinder carefully coated on both sides with fire-clay. It was fixed on a solid metal support, B, and the whole was surrounded with brickwork, C C. The lid was cast with two openings, E E, through one of which an earthenware pipe, c, descended nearly to the bottom of the cylinder, the lower end resting on hard burnt coke, with which the cylinder was filled. As carbon passed off during the operation, in combination with the sulphur, its place was supplied by fresh charges of coke, which were filled in through the other opening, E, in the lid. A metal arm, H, cast with the cylinder, was connected with a pipe, I, which was ground in at one end, the other passing into an earthenware carboy, J. A pipe with a cock, K, was attached to the bottom of the carboy, which carried the liquid into a Florentine receiver partially filled with water. This receiver discharged the bisulphide of carbon into a close vessel, O, by a pipe, M, from which it could be drawn off by a cock, N.

"The uncondensed vapour escaping from the carboy passed through another earthenware pipe, P P, to a worm G, made of zinc or earthenware, which was kept cool by a current of water. The bisulphide of carbon ran off at R into another close vessel, S, furnished with a cock.

"The space between the metal cylinder, A, and the brickwork, C C, is partially filled with fuel, which, when ignited, is supplied with air through the openings, D D, and the products of combustion escape at I.

"The fuel is now ignited, and the cylinder gradually heated until it becomes red, when pieces of sulphur are thrown down the pipe, c, at intervals of a few minutes. The sulphur is converted into vapour, which, coming in contact with the red-hot coke, combines with the carbon, producing the bisulphide of carbon.

"The cylinder," we are told, "lasts only about a week, and when made about 6 ft. long by 1 ft. diameter, it will produce about 2 cwts. of bisulphide of carbon per day."

This last statement is in itself a very serious matter, as to remove the old and replace a new retort the furnace must first be allowed to cool down, portions of the brickwork removed, and subsequently restored again and heated up to redness, which would entail the loss of at least one week's work; besides this the heavy expenditure in labour, fuel, and material, all of which expenses would have to be borne by about 14 cwts. of the product. At present retorts are constructed to make at least 4 cwts. of bisulphide per day, and which last 60 days and more, thus spreading nearly the same expense over a quantity about 17 times larger than the former, lessening its cost in proportion. I may also mention that at present charcoal is used exclusively, it having been found to yield larger quantities than coke.

The furnace itself is constructed on bad principles, as it would consume more fuel for a given result than would otherwise be necessary. Instead of surrounding the retort to nearly half its height with fuel, whereby the lower portion of the retort is liable to be kept cool and result in a less yield, the fuel ought to be burnt in thin layers on a grate, as in boilers, and the air admitted from underneath the grate only, and so arranged that the flame and hot products of combustion should circulate all round and the whole length of the retort. By this not only a greater calorific effect would be obtained from a given quantity of coal, but the retorts would be more uniformly heated, and yield a larger quantity of bisulphide. Again, by placing several retorts in one furnace a great saving is effected in fuel, labour, and general expenses.

A great loss in bisulphide must have been occasioned by the frequent removal ("every few minutes") of the lid, c, for the purpose of introducing the sulphur, not to speak of the inconvenience caused by the sulphurous acid vapours to the men attending to this operation. But the worst feature in this apparatus is its condensing arrangement. As already pointed out, considerable quantities of uncombined sulphur pass over with the bisulphide, crystallising out on their passage through the condensers and causing great annoyance. This sulphur has to be removed from time to time, hence the condensing arrangement ought to consist of straight pipes only, worm condensers being altogether inadmissible. In Peroncel's arrangement the carboy, J, is evidently intended to retain this sulphur; but although the greater part of it would condense here, sufficient quantities would be carried over into the worm, whence its removal would be impossible without destroying the worm itself, while the carboy would present similar difficulties.

There is yet another point that demands attention, and for which no provision seems to have been made in this apparatus. The charcoal contains a considerable amount of hydrogen, which gives rise to the formation of sulphuretted hydrogen. When the retort is freshly charged with charcoal, no bisulphide of carbon is formed until all the hydrogen present has passed off in combination with sulphur. Means must be provided to carry off, and if possible, to absorb, these deleterious vapours. How this may best be done will be shown further on.

Among those who improved most largely on Peroncel's arrangement, Deiss deserves special mention. In Stolman and Engler's edition of "Payen's Industrial Chemistry," it is stated that

24

within a few years he reduced the price of bisulphide of carbon from 2 francs per ounce to 50 cents per pound. At present it can be manufactured at a cost price of 1*d.* per pound or thereabouts.

Without stopping, however, to trace the successive improvements that have been made since Peroncel, I shall now describe what I consider to be the best apparatus of to-day. Having manufactured this substance, I am well acquainted with all the technical difficulties attending its production; and in the illustrations following I shall make various suggestions by which some of the sources of annoyance yet existing might be obviated.

I hope I may be pardoned for entering rather fully into details, in which I think I am amply justified by the industrial importance this substance has of late achieved, especially if we consider that our literature has not kept pace with its rapid development, and that but few of our handbooks describe its mode of manufacture, and those only giving more or less obsolete methods.

Fig. 2 shows a side elevation in section.

A is a vertical cast-iron retort, or, better still, made of earthenware, glazed inside, of elliptical shape, about 66 ins. high and 20 by 12 ins. internal diameter. It rests on a support, B, made of fire-bricks, and is protected by a mantle of best fire-bricks, C, about 4 ins. thick, leaving a space of from $\frac{1}{2}$ to $\frac{3}{4}$ in. between it and the retort. The metal of the retort should not be less than 2 ins. in thickness. D D is the outer brickwork of the furnace lined on the inside with fire-bricks, D' D'. E E, fire grates; E' E', ash-pits; F F, furnace-doors, made of frames, *f*, into which a fire-proof slab, *h*, is inserted. The furnace doors are suspended by cables running over pulleys, and are counterpoised, so that they can be raised or lowered. At *d* is shown a small peep-hole, through which the temperature in the furnace may be watched, a matter of the greatest importance, as we shall see presently.

In the lid of the retort are cast two tubes, G and G', of about 5 ins. internal diameter, and not less than 1 in. in thickness; but it is advisable to have them made somewhat stronger, as the lid will then outlast several retorts. Over the opening G, a vent-pipe or flue, H, is suspended by a lever, so that it can be raised or lowered at will, one end of which passes through the roof. When fresh charges of charcoal are to be introduced into the generator A, which is done through the tubulure G', the lid closing the tube G is first removed, and the vent-pipe, H, quickly lowered, which serves the purpose of carrying off the noxious gases that would otherwise be injurious to the workmen. G' may now be opened, and the carbon fed in without the slightest inconvenience.

From the tubulure G' issues a pipe, I, inclined upwards, through which the bisulphide of carbon vapours escape. Most of the free sulphur passing over will condense here and run back into the retort. But the partially cooled sulphur falling on to the surface of the incandescent carbon would be immediately vaporised again, at the same time cooling down the top layer of the charcoal. To obviate this, I would suggest an opening should be made in the lower part of the pipe I, to which a hopper can be fitted, as shown at J, terminating in an earthenware pipe, K, reaching nearly to the bottom of the retort. By this means the sulphur distilling over uncombined would be conducted back to the bottom of the generator, the pipes would be less liable to be choked up, while the resulting product would be purer.

From the lower end of the retort, close to the bottom, a pipe, M, is branching off, a little upwards inclined, passing through the brickwork, and terminating in a chamber, N, with door *n*. During work this pipe is carefully closed by a lid. It serves the purpose of raking the ashes out of the retort, which is done once a week. At *m* a flue is shown, carrying the noxious gases into the chimney. The ashes are allowed to cool here before their removal. Adjoining this chamber is a hearth into which an iron vessel, O, is fitted, for melting the sulphur. It is heated by a flue from the furnace passing underneath it, provided with a damper to regulate the heat. (In Fig. 2 this sulphur vessel is raised so as to make it visible in the drawing.) A pipe, *o*, closed by a conical valve to which an iron rod *o'* is attached, connects the sulphur pot with the arm, M, of the retort, by which means the sulphur can conveniently be introduced into the latter.

The sulphur flowing down the incline of the arm, M, arrives at the bottom of the retort, where it is volatilised; the vapours passing upwards, combine with the carbon. The generated bisulphide vapours escape through pipe I, and then pass down the vertical tube, P, into a vessel, P', where any excess of sulphur is deposited. The lid of this vessel rests in hydraulic seals, and is connected with the inlet and outlet pipes by a kind of telescopic tubes made air-tight by water, as shown in drawing. When the vessel, P, is to be removed, the lid is raised, the vessel taken away, another similar one put in its place, and the lid lowered again. This should be done once a week only, and never while distillation is going on.

The bisulphide of carbon vapours, now freed from the greater part of uncombined sulphur, pass through a Liebig's condenser, G, about 30 feet long, into a receiver, S, partially filled with water. The cross-piece, T', connecting the Liebig's condenser with the receiver, is made so that it can be detached—being secured at *v* by flanges bolted together, and at *v'* by water seal—for purposes of cleaning, &c. From here the bisulphide is allowed to run through a syphon, *p*, direct to the storage tanks. A better plan, however, is to keep the storage tanks for the crude product on a high level, which greatly facilitates the after process of purification. In this case the bisulphide of carbon is allowed to flow into a *montejes*, U, as shown in drawing. A pipe, *q*, reaching nearly to the bottom, is passed through the cover of the *montejes* to the high-level tank. A second pipe, *r*, connects the vessel U with a force pump. On air being pumped into U through *r*, the stop-cocks *p*¹ and *p*² having been shut off, the bisulphide is pressed up through pipe *q* into the tank. This is a far better method than using pumps, as in the latter it is difficult to prevent leakage, the crude bisulphide having a very corrosive action on most metals. For the same reason the receivers, tanks, &c., for the crude substance should all be lined with sheet-lead, as wrought-iron vessels soon perish, while copper is even more energetically acted upon. Cast iron withstands corrosion much better, but is objectionable on account of its porosity. This might be remedied, however, by giving the vessels repeated coatings of dilute silicate of soda, both inside and outside, the vessels being first slightly heated with steam and the silicate applied while warm.

Near to the top of the receiver, S, is a pipe, *s*, for carrying off the uncondensable vapours—chiefly sulphuretted hydrogen. The gases are conducted into a rectangular vessel, W, where they are made to circulate in zig-zag over a series of shallow trays filled with a vegetable oil, to absorb any bisulphide

vapours which have escaped condensation. The oil can be made to trickle from a reservoir, H, as shown, through a goose-necked pipe, which, passing from tray to tray in an opposite course to that of the gases, finally trickles through X into a receiver, Y. When a sufficient quantity has accumulated here, the bisulphide is distilled off and the oil returned to X. Before the gases enter this absorber, they are "washed" by making the end of the pipe *s* dip into the oil as shown at *y*, whereby the apparatus is disconnected from contact with air. The gases are now passed through a second vessel, Z, similar in construction to the one just described, only substituting lime or oxide of iron for the oil, to absorb the H_2S , and are then allowed to escape into the open air through the pipe *z*.

Above the retort, A, and between it and the chimney set at right angles to each other, is a smaller retort, similar in construction to A, but only about one-third the capacity of the latter, and is heated by causing the products of combustion coming from the furnace to circulate round it before finally passing into the chimney. (Only the discharge hole, *h'*, corresponding to the arm *m* of the retort A, is visible in drawing.) As the generator, A, requires fresh charges of carbon every eight hours, it is very economical to keep this small retort always filled with charcoal, which by the time it is required will be red hot, and no more time need be lost than is required for transferring it from the one into the other retort. By this arrangement part of what would otherwise be waste heat is utilised, and a great saving in time and fuel effected. A still better plan is to make the charcoal on the spot, eight hours being more than sufficient to char the wood and to heat it up to bright redness. The spent dye-woods, tanners' refuse, or sawdust are excellent for the purpose, and as these would not require crushing—as when charcoal is bought in lumps—a saving in labour, possibly also in money, might be made, besides being more cleanly. By a small outlay the vapours might be condensed, and pyroligneous acid obtained as a by-product. I have used the sawdust from sandal wood, from which the oil had previously been extracted, for making charcoal in this way, with good results.

The apparatus is worked as follows:—After having allowed the brickwork to set and partially dry for a few days, the fires are started, at first gently, to prevent the brickwork from cracking, then gradually increasing the heat, until the retort becomes a dull red colour. The latter is now filled with small charcoal, and the smaller retort with chips, sawdust, &c., and the fires are now urged on until the retort and the charcoal in it have become a "cherry red." This heat should never be exceeded, nor should it be allowed to fall below this, as in either case it would result in a lesser yield of CS_2 . Sidot experimented with specially prepared charcoal at various temperatures, in each case employing 10 grms. of carbon and 40 grms. of sulphur, with the following results:—

Temperature.	Loss of Carbon.	CS ₂ .
	Grm.	Grm.
Dull red heat.....	5	17
Red heat.....	6.3	29
Bright red heat.....	7.5	19

or for a uniform loss of 5 grms. carbon in each case he obtained 17, 23, and 12.7 grms. of CS_2 respectively. These experiments—borne out by the practical experience of the manufacturer—show conclusively

the great importance of maintaining the heat at or about the proper temperature, which is not difficult if intelligent and reliable men are employed.

On having attained the proper temperature, the two openings in the lid of the retort are closed, the lids being screwed down tightly, with some clay made into a thick paste as a lute. I have found it difficult, however, to make good joints in this way, there often being a ring of a pale blue flame round the edge of the lids. A better way would be to cast in the top of these tubulures grooves, and the lids with a rim loosely fitting into these grooves, forming what is called a hydraulic seal, only using lead in the place of water. The heat there is sufficient to melt lead, but not so great as to prevent its use. This would form a much better lute, and could be opened and closed in much less time, which, in the case of bisulphide of carbon manufacture, is a great desideratum. Having previously secured all the joints throughout the apparatus, sulphur is now run in by raising the rod *o'* in the sulphur pot. A bubbling will immediately be heard in the gas-washer at *y*, caused through the escape of sulphuretted hydrogen, &c. In a few minutes this bubbling ceases, and CS_2 begins to distil over. Distillation is now proceeding, sulphur being charged in every five minutes, about 1½ to 1¾ lbs. each time, for seven hours, when the supply of sulphur is stopped, and one hour allowed to elapse before fresh charcoal is filled in. The lid is then removed from G, and the flue-pipe, H, lowered. G may now be opened, and lastly of all the lid *h'* is removed from *h* of the carboniser, and the red-hot charcoal raked from the carboniser, by means of a funnel or hopper, into the retort A. The retort is now closed, taking care that the openings communicating with the flue H is the last to be shut off, and work started again. At the end of each week neither coal nor sulphur is charged in for eight hours, after which the whole apparatus is cleaned out in the following manner:—

The flue H having been lowered on to G as described above, the cover *k* at the end of the delivery pipe, I, is removed, and wet bags or pieces of canvas are tightly rammed down the pipe I, and past its junction with the vertical pipe I', so as to isolate the condensers, &c. from the furnace. The ashes are now raked out through M, as described above, the retort refilled with fresh charcoal, and while this is getting heated up, the other portions of the apparatus are examined, and where sulphur is present it is removed.

With one such retort from 4 to 5 cwt. of CS_2 can be made per day, but it is much more economical, both in labour and fuel, to have several retorts—say four—in the same furnace.

The Purification of CS_2 .

The product obtained by the above process contains considerable quantities of sulphur in solution, also a large amount of H_2S and other sulpho-compounds, which impart to it a pale yellow colour and a very disagreeable odour. Of these impurities it can be easily freed by careful rectification, leaving a colourless, mobile, liquid, of an odour not at all disagreeable, and resembling that of chloroform. Commercial CS_2 is seldom pure, and in many instances differs from the crude substance only in containing a lesser quantity of free sulphur, while nearly all the other impurities which impart to it that disagreeable smell are still contaminating it. From the latter it cannot be freed by simple distillation, as the H_2S and other gases distil over with it and are re-absorbed during condensation.

From the many methods that have been suggested for its purification I shall describe the one only which alone can be employed on the large scale, the others being too expensive for commercial purposes without offering any special advantages.

I have employed the following simple method with very satisfactory results:—

A cylindrical vessel, about 30 inches in diameter and 6 feet high, is provided with a perforated coil of lead pipe at the bottom. Into this vessel I run the CS_2 to be purified to about one-third its height. I then pump lime-water into it, the latter being introduced into the vessel by means of a force-pump through the perforated coil. The lime-water, being specifically lighter than the CS_2 , rises to the surface, and while traversing the body of the bisulphide in a finely divided spray, the lime combines with the H_2S , &c. I continue this washing until the lime-water, which leaves this vessel through an overflow pipe near to the top, is perfectly clear. The CS_2 is now run into a still, about 1 per cent. its weight of a cheap, colourless oil added, and covered with a layer of about one inch of water, to which some sugar of lead may be added. The CS_2 is now distilled in a water-bath and condensed in the usual way. A very pure product is obtained in this way. I have treated in this way CS_2 bought from a Manchester maker, which was supposed to be "rectified." Its specific gravity was 1.292; after having washed it in the above manner it had a specific gravity of 1.289, which was reduced to 1.286 after distillation.

As the various handbooks on chemistry give ample information as regards the properties of this interesting compound, I shall not extend the limits of this paper by describing them, but will conclude by enumerating some of the leading uses to which it is already put. This list is by no means exhaustive, and is rapidly growing.

I. For the extraction of fats and oils from seeds, &c.

II. For the extraction and recovery of oils and fats from bones, stearine-waste, dried axle grease, the pressings (greaves) from tallow, sanza (the husks of the olives after leaving the presses), and a large number of other waste products.

III. From rags and cotton-waste used for cleaning machinery, leaving both oil and rags in a fit state for re-use.

IV. For cleaning wool and recovering the fat therefrom.

V. As a solvent for chloride of sulphur in vulcanising caoutchouc and in waterproofing.

VI. For the extraction of sulphur from poor ores, which used to be thrown away as being too expensive to extract by the old process.

VII. For the recovery of grease from soapsuds in wool-washing.

VIII. For killing weavils in grain. (A small quantity mixed with the grain in a closed chamber is said to kill even the larvæ.)

IX. In Australia it has been very extensively used for killing rabbits.

X. An emulsion of CS_2 with water, which is easily made by the addition of a small quantity of sulpho-ricinoleate, is used for killing parasites on plants, and is largely used in France and Germany for the extermination of the *phyllorhiza vastatrix*.

XI. In electro-gilding, as a solvent for phosphorus.

XII. In prisms, on account of its great refractive power.

Of late it has been proposed for use in steam-boilers instead of water, and several devices have recently been patented for the purpose.

CS_2 is also very useful for producing low temperatures and as an anti-putrescent.

DISCUSSION.

The CHAIRMAN remarked that, although Mr. Singer had addressed himself specially to those engaged in this industry, no one could have listened to his graphic account of the process without deriving considerable benefit and pleasure. If Mr. Singer could, in his investigations on bisulphide, discover a practicable method by which such bodies could be eliminated from coal gas, he would confer a great benefit, and especially on the people of that district.

Mr. H. L. TERRY had had some experience in the use of carbon bisulphide, and referred to the frequent occurrence in it of sulphuretted hydrogen. He had heard that this impurity was produced in the carbon bisulphide on standing, and he wished to know if Mr. Singer had noticed this to be the case. With regard to the explosive properties of this substance when its vapour was mixed with a certain volume of air, he had had convincing proof of this, as during one of the recent fogs a quantity of the vapour collected, and was exploded by a spark, doing serious damage to property. Users of this body were not sufficiently aware of this danger. Nothing had been said as to the deleterious physiological effects of the vapour. His experience was, that if some substitute could be found for it, it would be the better for the health of the workpeople who were brought in contact with it.

Mr. GEORGE E. DAVIS thought there could only be one opinion as to the great technical value of bisulphide of carbon. It showed, perhaps better than anything else, how necessary it was to follow up the process from the beginning. In the erection of chemical plant on a large scale, sufficient consideration was not given to the danger arising from defective construction causing an accumulation, through the apparatus becoming choked, and the necessity of making a hole to admit of an escape.

Mr. WATSON SMITH said that for scrubbing the final gases from the apparatus, coke-packed scrubbers were fixed at the end of the system with which he had worked, and filtered anthracene oils were allowed to flow down them. The oil was afterwards collected and steamed. Thus, bisulphide of carbon was recovered and sulphuretted hydrogen removed in the condensed water. With regard to the methods for preventing the bisulphide of carbon affecting those who came in contact with it in india-rubber works, he thought Mr. I. Frankenburg deserved great credit for covering over the channels conveying the bisulphide, and other apparatus with glass, in order to prevent the fumes from affecting his workpeople. A slow draught was thus caused to circulate through the system, so that bisulphide vapours could not escape, though air might be slowly sucked in.

Mr. SINGER, in reply, said he would rather use bisulphide of carbon than any other substance. It had the advantage of being heavier than water, and if fairly used, with proper apparatus, nothing was easier to handle.

ANALYSES OF SALT STALACTITES.

BY PROF. P. P. BEDSON.

PROFESSOR BEDSON communicated the results of analyses of stalactites of salt, found in some of the disused workings of Redhenge Colliery, Gateshead. The stalactites were of considerable length, some colourless or white, others reddish-brown. The analyses were executed by Mr. W. H. Dunn, junior, a student in the College of Science, and the following are the results:—

Results of analysis of the white salt, which was entirely soluble in water:—

Moisture	0.28
Magnesium	0.04
Calcium	0.19
Sodium	39.06
Chlorine	60.11
	<hr/> 99.95

Chlorine required..... 60.16

Analysis of brown salt stalactites, not entirely soluble in water. The insoluble matter consisted chiefly of ferric oxide:—

Moisture	0.28
Insoluble matter	0.69
Magnesium	0.03
Calcium	0.16
Sodium	38.81
Chlorine	59.81
	<hr/> 99.78

Chlorine required..... 60.11

Professor Bedson afterwards conducted the members through the rooms of the chemical department of the new building of the College of Science, and explained the various provisions and devices to facilitate lecture and laboratory work. A hearty vote of thanks was awarded to Dr. Bedson.

A NEW VALVE ARRANGEMENT FOR REGENERATIVE FURNACES.

BY H. LE NEVE FOSTER.

THE invention of the regenerative gas furnace by the late Sir William Siemens, and its application for the manufacture of open-hearth steel, glass, and heating purposes, &c., &c., has necessitated a valve

by means of which the inlet of gas and the outlet of products of combustion can be reversed at will.

For this purpose Sir William Siemens designed what is termed the butterfly valve, which has been used for a number of years. The disadvantages of the butterfly valve are that the flap or butterfly becomes hot and warps, and consequently there is a leak of gas to the chimney, which becomes larger and larger until the flap has to be replaced at considerable inconvenience.

Sir William Siemens in his original furnaces used as a rule to recommend the use of cooling tubes, and in some of the works erected by him these cooling tubes were several hundred feet long, so the gases were comparatively cold before passing through the valve; at that time there was not nearly so much trouble with the valve. Now the most modern works have abandoned cooling tubes as much as possible, all tubes being lined with brickwork, so that the gases pass through the valves at a much greater temperature. I think I am correct when I say that all the open-hearth steel works in the North of England, which has now become the largest centre for the manufacture of mild steel for shipbuilding purposes, have abandoned the butterfly gas valve for their melting furnaces, though this class of valve is still used for reversing the air current, and, for this purpose, answers admirably.

The double mushroom valve is now being used, but this also has many drawbacks and does not work as satisfactorily as it should do, consequently the seats and valves themselves often have to be replaced.

I will now describe the accompanying drawing, which illustrates partly in sectional view, and partly in elevation, a set of valves, a^1, a^2, a^3, a^4 , with their operating mechanism, two valves being provided in the usual position in each of the flues or passage b^1, b^2 , that is one above and the other below the branch flues or passages, c^1, c^2 , through which the gases are admitted to the passages b^1, b^2 , or escape therefrom as the case may be.

In the drawing the valves a^1, a^4 , are closed, and the valves a^2, a^3 , are open. In this position of the valves the gases are passing from passage c^1 into the vertical passage b^1 , have their course diverted downwards as indicated by arrows, whilst the escaping gases entering passage b^2 from above, have their course diverted into the branch passage c^2 also as indicated by arrows.

If the position of the valves is exactly reversed it is obvious that the direction of the currents through the passages will be correspondingly changed, and that by reversing the valves from time to time the requisite succession of changes in the current of the gases can be effected in the well-known manner required in working a regenerative furnace. In order to operate the valve simultaneously the valves in the passage b^1 are fitted in the position so as to be exactly opposite respectively to the valves in the passage b^2 , so that by connecting the spindles d^1, d^2 , of the valves a^1, a^2 together, and the spindles d^3, d^4 , of the valves a^3, a^4 , together, the valves can be coupled together in pairs in the manner illustrated in the drawing. By providing suitable mechanism, such as a spur wheel mounted on a spindle in such a position as to gear into racks provided on the valve spindles, that is one rack fixed to the united spindles d^1, d^2 , and the other rack to the united spindles d^3, d^4 , the valves will be all operated together by the rotation of the spur wheel, and will be moved in the required manner, that is the upper pair of valves a^1, a^2 , in one direction, and the lower pair of valves a^3, a^4 , in the opposite direction, thus affording the requisite control of the passages between the regenerative chambers and the furnace. It is, of course, obvious that

other means can be devised for operating the valves in the same manner, as for instance by a hydraulic motor applied in the manner illustrated in the drawing, in which c^1, c^2, c^3, c^4 are hydraulic cylinders provided in the positions shown for the reception of the plungers f^1, f^2 , which are secured by means of coupling pieces g^1, g^2 to the valve spindles, so that any motion imparted to the plungers is simultaneously shared by the valves. h^1, h^2, h^3, h^4 are pipes communicating from the pump i to the cylinders c^1, c^2, c^3, c^4 , that is, water pumped into pipe h^1 enters the cylinder c^1 , and by means of pipe h^2 at the same time enters the cylinder c^4 , thus driving the plunger f^1 in one direction, and the plunger f^2 in the opposite direction. Similar water pumped into the pipe h^3 drives the plungers back again.

This is the plan I myself prefer, and is now being used in the valves which have been erected by the West Cumberland Iron and Steel Works; these valves have also been supplied with a water-jacket. This tends to keep the valve-casing from getting red-hot. These valves have now been in use some considerable time, and there is no leakage of gas whatever, and up to the present time they have required no repairs whatever, though some double mushrooms valves which were put in at the same time have had their mushroom replaced.

Another advantage is that there is a considerable saving in fuel. A new furnace with my valve arrangement only required one block of producers, that is four fires instead of two blocks of producers or eight fires, which were required for smaller furnaces next to it.

I think this helps to show that the waste of gas through a leaky valve is much more than one would anticipate.

Notices of papers and communications for the meetings to be sent to the Local Secretary.

Errata.

In Mr. F. J. Rowan's paper on "Evaporation by Multiple Effect," in the January number of the *Journal*, the illustrations Figs. 1 and 2 were accidentally transposed. Fig. 1, p. 33, which purports to be the Smith triple effect apparatus, is really a view of the Yaryan evaporator, and Fig. 2, p. 34, is the Smith triple effect apparatus, not the Yaryan evaporator as stated.

In the 2nd column, page 32 of the same paper, lines 16, 17, and 18 should read as follows:—"and of those for dealing with liquids, the stills of Dorn, Derosne, and Coffey illustrate the class," &c.

The Fourth Meeting of the Session was held in the Rooms, 14, South St. Andrew Street, Edinburgh, on Tuesday, 5th February 1889.

MR. GEORGE BEILBY IN THE CHAIR.

THE MANUFACTURE OF PARAFFIN OIL.

BY D. R. STEUART, F.I.C., F.C.S.

THERE have been several papers on shale distillation and paraffin extraction read before the Society of Chemical Industry, but there has been no description given of the general operations of refining. In this paper I mean to give a short sketch of the whole paraffin oil manufacture as carried on at Broxburn, and in such a manner that outsiders, who at present know nothing of the subject, may get a general notion of all our methods of working. Many members of the Society visited the works last year, but only a small proportion I think, could have heard the explanations given. I shall have to go over ground familiar to anyone that has taken any interest in the manufacture, and describe apparatus and operations that have been described elsewhere, but in publications difficult to get at.

On the table I show samples of the bituminous shale from which we get all our products, and of the products themselves: sulphate of ammonia, naphthas, burning oils, lubricating oils, solid paraffins, gas oils, still coke. The naphthas are 730 and 740 sp. gr.—used as solvents, for burning in special lamps and for paraffin refining; the burning oils are 7800 to 7840, and the lubricating oils 7865 to 7895. There is soft paraffin, melting point 100° F., used largely for dipping the sticks of matches and for hand-lamps, and paraffin wax, semi-refined and refined, with melting points from 118° F. to 130° F., used for candle making. Solid paraffin and paraffin oil are now much used for washing clothes.

The shale field, which since 1877 has been worked by the Broxburn Oil Company, Limited, was taken on lease by Mr. Robert Bell in 1858, and in 1861 the distillation of the shale was in full operation. This was the beginning of the shale industry in Scotland. For the 10 years previous to this, during which the paraffin oil manufacture had existed, the Boghead or Torbanehill coal was the mineral used. This mineral gave 120 gallons of crude oil per ton. In 1862 it ceased to be worked for paraffin oil, and it was soon after completely exhausted.

The shale we work at Broxburn at present is what is known as the Broxburn seam. Its position geologically is in the lower carboniferous series, 740 fathoms or so above the Camps or Burdiehouse limestone (see Journ. VI., 128). There are seven other seams at least worked in the Lothian shale field, and these lie some above and some below the Broxburn seam, and within 300 fathoms of it. They vary in thickness and quality in different districts, what is thick and rich in one district being poor or thin in another. The shales differ in character also, the Pumpherston seams, for instance, being poor in oil but rich in ammonia. The Broxburn seam averages in the Broxburn Oil Company's field about 5 feet in thickness, part of this thickness giving over 40 gallons per ton and part little over 20 gallons. It is worked in the same manner as coal. Where the retorts are placed there is none of this

seam below, but it comes to the surface all round quite close to the works, and can be worked open-east. It gradually gets deeper, and mines are sent out radiating in all directions to get the shale at hand. The shale from these is brought by wire-rope arrangement in the mine hutches direct to the breaker, and the platforms for the hutch-railways are a conspicuous feature in the first glance at the crude oil works. Pits are sunk in various directions a mile or two further out to get the deeper shale, which is brought to the breaker by railway. The shale all passes through the breaking machines, where between two toothed iron rollers it is broken into pieces the size of a fist. The shale falls from the breakers into hutches, which are taken by endless rope to the top of the retorts, and tipped directly in. Manual labour is done away with as much as possible.

The first chemical process of the works is the destructive distillation of the shale. The shale contains by analysis: carbon, 20 per cent.; hydrogen, 3 per cent.; nitrogen, 0·7 per cent.; sulphur, 1·5 per cent. The compounds of these elements are no doubt of vegetable or animal origin. On treating powdered shale with shale naphtha or ether, the solvents remain quite clear and colourless, and dissolve nothing, proving that our products do not exist in the shale as such, but are all created by the destructive distillation. About 1,000 tons of shale are distilled at Broxburn per day, and the products are—

Volatiles:	Per Cent.
Crude oil.....	12
Ammonia water.....	8
Permanent gas.....	4
	24
Non-volatile (spent shale):	
Combustible.....	9
Ash.....	67
	73
	100

To get a good quality of crude oil the temperature of distillation must be low, a red heat invisible in daylight and faintly visible in the dark. In general, a higher temperature produces a heavier darker crude oil, giving more loss in refining, and less solid paraffin, but a higher yield of ammonia. The only retort now used at Broxburn is Henderson's patent retort. Of these there are 784, arranged in 16 benches. As you see from the drawings (Fig. 1) it is a vertical retort. It is of cast iron, 14 in. thick, 15 ft. long, and of oval section 2½ ft. by 1 ft. The charge is 18 cwt., and it lies in the retort for 16 hours, distilling off the crude oil, ammonia-water, and permanent gas. After this the spent shale, which still contains 12 per cent. of combustible matter, is dropped hot into the furnace below to act as fuel. Four retorts are built into one oven and are connected with the one furnace, one retort being dropped every four hours to keep up the succession of heat. The products of combustion are taken off at the bottom of the oven instead of the top, so as to produce the gentle draught required by the weak fuel. The permanent gas of the distillation is also burned as fuel. It used to be passed among the spent shale, but it is now burned in the bottom of the retort oven. Steam, superheated by passing through pipes in the oven, is passed into the top of the retort. It introduces the right temperature throughout the mass of the shale, and sweeps the distillation products rapidly out of the heat, where they would undergo decomposition. No coals are required for fuel, except to make a start after a

Fig. 1.

stoppage. The products pass off from the bottom of the retort to the main and condensers. The condensers are a series of vertical iron pipes cooled by the atmosphere. The crude oil and ammonia-water flow from the condensers through a small vessel called a separator, where they at once part from each other by gravitation, the oil being the lighter, and pass into their several tanks. The non-condensable gases are drawn up through large towers, where they are washed, by water trickling down, from any remaining ammonia. Some naphtha is here condensed by the cold of the water, but several gallons of light naphtha per ton of shale, which we used to catch in blue oil, are at present allowed to go with the permanent gas. There are fans to suck the products from the retorts. After the spent shale has been burned, the bottom of the furnace folds down so as to drop the ash into an iron hutch below. The hutch with its glowing contents is run into the pond for dirty water, which it causes to evaporate, and after being quenched

the residuum is taken by endless rope to the refuse bing.

This retort gives, without skilled labour or particular attention, the right temperature for making good crude oil. The mild temperature prevents the yield of ammonia from being nearly so high as it is with some high temperature retorts; but against this defect we have the long life of the retort, the good quality of the crude oil, and the economy as to fuel. The temperature of the oven is from 900° to over $1,000^{\circ}$ F.; the steam as it goes into the retort 630° F.; the shale inside the retort, 1½ ft. from top, three hours after charging, 630° F., 16 hours after charging 730° F.; and the products of distillation at the exit pipe 500 to 600° F.

It has often been suggested that reagents should be put into the retorts in order to get an increase of ammonia and a purer crude oil; but as far as my experience goes with this particular retort, neither lime nor soda has any appreciable effect of any kind, and the dust, when the spent shale

was dropped, made it very painful for the men. Solid reagents in the quantities that can be given on the large scale do not seem to come into sufficient molecular contact with the vapours. Gas reagents may be considered a little more promising. Mr. Tervet (*Journ. II.*, 445) got a greatly increased yield of ammonia by passing hydrogen into retorts at the end of the distillation. Mr. Irvine, by passing ammonia through retorts when the shale contained sulphur, got an increase in the solid paraffin. And Mr. Beilby got an increase of paraffin by passing air into his retort (*Journ. III.*, 220). In the Young and Beilby retort the large yield of ammonia from the hot part in passing through the part of the retort distilling the oil may help to give a higher yield of paraffin than would otherwise be the case at such a temperature; but how can air increase the paraffin? Can any of the oxygen reach the distilling oil so as to act on the sulphur or otherwise, or does the air act only by modifying the temperature?

A gas reagent used in all retorts is steam. It acts mechanically in protecting the ammonia and the complex hydrocarbon molecules from decomposition. At 1,000° C., according to Ramsay and Young, ammonia in presence of iron is nearly completely decomposed into its elements; but where steam is used in excess, as in the Groven method of analysis, all the nitrogen of organic compounds is at this temperature converted into ammonia, sulphur appears as sulphuretted hydrogen, the oxygen combines with the carbon, while some hydrogen is left free. Steam at such a high temperature is a powerful chemical reagent. At the comparatively low temperature of the Henderson retort its action is very gentle, but it does act on the carbon to some extent to give nascent hydrogen to help to build up ammonia and solid paraffin, and the yield of these is a good deal more than in the old vertical retorts worked at the same temperature.

Of the 1.5 per cent. sulphur in the shale, more than 1.4 per cent. remains with the spent shale when dropped from the retort, and 1 per cent., even after burning; 0.025 per cent. goes to the permanent gas, 0.028 per cent. to the crude oil, and 0.02 to the ammonia-water.

The nitrogen in the shale is equal to 70 to 90 lbs. of sulphate of ammonia per ton of shale. Of this we get no more than one-fourth, while nearly one-half remains with the spent shale. Mr. Beilby has studied the nitrogen very carefully in connexion with his retort products. (*Journ. III.*, 216.)

I got samples of crude oil taken from a retort every two hours, and tested specific gravity, setting point, loss with oil of vitriol, and loss with caustic soda. I found there was a gradual increase throughout in the specific gravity—from 863 to 888, and in the setting point—from 78° to 87° F. The loss with oil of vitriol gradually increased from 5½ per cent. at the beginning to 10 per cent. in the middle, and then fell to 5½ per cent. at the end. The loss with soda gradually increased from 2.6 per cent. to 3.8 per cent. The quantity of oil coming for some hours at the end was comparatively small.

Each ton of shale produces in the works on an average 30 gallons of crude oil, 65 gallons of ammonia-water, and nearly 2,000 cubic feet of permanent gas.

The permanent gas is sufficient in quantity to light up the crude oil works, fire the retorts along with the spent shale, and have a considerable quantity left to help to raise steam.

The crude oil is of a dark-green colour. It is semi-solid at ordinary temperatures, quite fluid when

gently warmed, but setting or ceasing to flow at 80°, from the amount of solid paraffin in it. Our crude oil averages about .865 in specific gravity. The crude oil of other works is sometimes .880 or .890 sp. gr. Our own shale distilled in the gasworks at a red heat gave about 4,500 cubic feet of rich gas; nine gallons of crude oil of .952 sp. gr., which was a thin mobile liquid, containing little solid paraffin, and 8½ lbs. of sulphate of ammonia per ton. The small yield of ammonia shows the influence of the high temperature in the absence of steam.

The ammonia-water averages 21° Tw., or sp. gr. 1.012. It contains ammonia equal 0.277 lbs. of sulphate per gallon, principally in the form of carbonate. There is a small proportion of sulphur present as sulphide, and traces of sulphite, sulphate, and thiosulphate; but no cyanide or sulphocyanate. The amount of fixed ammonia is small, and no lime is used in the distillation. The still we use is a column still of the form shown in the drawing (*Fig. 2*), 22 ft. long, 5 ft. in diameter, and with 14 trays. The three upper trays are open-topped annular channels; and the rest consist of an annular outer part, a disc-shaped central part, and a space between covered by an inverted piece which dips to the bottom of both the annular part and the disc part. The inverted piece is notched below, up to within half an inch of the surface of the liquid in the tray. The ammonia-water enters at the top, flows from tray to tray, and is discharged at the bottom exhausted. Steam of 25 to 30 lbs. pressure, introduced by a 2-in. pipe at the bottom of the column, rises through the space surrounding the disc, and passes through the notches of the inverted piece to bubble through the water of each tray. The system is a continuous one, and 35,000 gallons are passed through each still per day. It is found to be very economical in regard to labour and fuel, as well as in first cost of plant.

The volatile ammonia compounds are passed from the still into weak sulphuric acid. This acid has been used for refining the oil, and has been separated from the bulk of the tar with which it was combined. There are still strong bases in solution, and these are precipitated by the ammonia in the saturator-boxes in the form of a black tar which rises to the surface. After separating the tar, the solution of sulphate of ammonia is evaporated down in vessels heated by coils of steam pipes. The salt as it separates falls to the bottom and is fished out with a perforated ladle, and put up to drain and dry. In several days it is ready to be passed through a crushing mill into bags for the market. Neutral sulphate of ammonia on boiling gives off a little free ammonia, so the evaporating solution is always slightly acid in reaction. The temperature of the boiling solution rises to 225° F. Our sulphate is of a grey colour from a trace of impurities got from the acid. When the ammonia gases are passed into oil of vitriol, white sulphate of ammonia separates out and is fished direct from the saturator-box. It was at Broxburn that ammonia was first made from the ammonia-water of this manufacture, viz., by Mr. Robert Bell in 1864.

The operations of the oil refinery are (1) distillations; (2) treatments with chemicals; (3) cooling and pressing the heavy oil containing paraffin so as to separate the solid from the liquid.

The oil all gets several distillations—for purification, and for thorough fractionation of the different gravities of oil from each other. Between the distillations the oil is treated first with oil of vitriol, and, after settling, with caustic soda, and these separate all the compounds present except the products which

Fig. 2.

we want. The old method of refining was, first, to distil to dryness in cast-iron round-bottomed stills. Naphtha came over first below the temperature of boiling water, the temperature gradually rose, distilling light oils, intermediate oils, heavy oils and paraffin, until at the end, when still-grease came over, the bottom of the still was of a red heat. After cooling, the coke left in the still, 1½ ft. thick or more, was cleaned out and the still was recharged. In some works the distillation was stopped short of coking, and the residue run out as pitch. After chemical treatment the oil was redistilled from stills of malleable iron, which from their shape are called boiler stills. When the distillation was fairly started, oil was run into the boiler still, which kept distilling lighter oil only, until the heavy oil accumulated in the still, when the feed of oil was stopped and the heavy oil distilled off until there were only a few inches left. The firing was stopped, and the residue, after cooling a little, was run into a coking still (similar to crude stills) to be distilled to dryness. The boiler still was cooled, cleaned out, and recharged. The stills in this old system were all half their time cooling down, cleaning, and heating up. Steam was used in all the distillations, and had to be constantly altered as the distillation proceeded, and its manipulation often caused the still to froth over into the distillate and pollute it.

The present system of distillation is a continuous one, in which the stills are connected together into a series. One set of drawings show (Fig. 3) wagon-shaped stills connected with residue or coking stills, such as we use for crude and lubricating oils. Let us take the crude oil as an example. The wagon-shaped stills are charged up at first (2,000 gallons) and the fires lighted, and when distillation is commenced the cocks on the connecting pipes are opened, and the feed oil is run into the central still I. The feed is always heated on its way to the first still by the vapours of the distilling oil in a feed-heater of special safe construction shown in the drawings. Still, I, receives the oil at the front, and the oil travels along the length of the still, distilling off "green naphtha" of 753 sp. gr., which is condensed by an ordinary worm-tank condenser. The oil not distilled in passing through still I., is conveyed by pipes which proceeds from the back of this still to the back of stills II. and along the length of stills II. till they empty themselves at the front. The oil travels along these boilers distilling off a higher boiling fraction, 835 sp. gr., and from the back of II. a pipe conveys the concentrated oil to the residue or coking still III. The hot oil is run into an empty coking still, which for safety has been previously fired up gently, and the air thoroughly blown out with steam. One of these stills remains connected in the series for eight hours, when it is disconnected and distilled to dryness by itself, and another coking still takes its place. The distillate from these stills runs from 860 sp. gr. to 965. This set of stills can put through 35,000 gallons of crude oil per day.

Other drawings (Fig. 4, p. 107) show three ordinary boiler stills connected with each other and with residue stills. The old form of boiler stills can be cheaply connected in this way. This kind is used at Broxburn for all the after distillations except that of the lubricating oil. The charge for each still is 3,000 gallons.

Steam, more or less, is passed into all the boiler stills. There is considerable power of adjustment as to gravities of distillate by the cocks on the connecting pipes, the firing and the steam, and once adjusted they require little altering. There is no

danger of frothing over. Stills connected in this way can put through twice as much oil as when worked each by itself on the old plan. There is great saving in labour and fuel, as the boiler stills never require to be stopped or cleaned, and so do not require to be cooled down and heated up. There is also less cost in maintenance, as they are not subjected to the contractions and expansions of the cooling down and heating up of the old system. The fractionation is also more perfect and the distillates purer, giving less loss in refining, as the oils are always distilling from comparatively pure oils, and not, as in the old system, from concentrating impurities. For the last nine months our total loss in refining the crude oil has been only 26·7 per cent.

The stills have behind them a row of charging tanks raised above the level of the stills so that the feed oil runs from them to the stills by gravitation. Behind the charging tanks there is a row of tanks on the ground to receive the various distillates. Where it is possible the stills are arranged so that the products of combustion from one still requiring a high heat are used for firing another still requiring less heat.

When the crude oil is pumped from the retorts to the refinery it first gets a distillation, and by it is fractionated into green naphtha and green oil with gravities of 753 and 858, the distillates of stills II. and III. being run together in our present way of working. The naphtha gets a treatment with chemicals and a distillation, and is then ready for the market. The green oil is treated and distilled, fractionating into light oils and heavy oils containing solid paraffin. The light oils require one or two treatments and distillations to make them ready for the finishing treatment. The heavy oil and paraffin after cooling and separation of the solid paraffin is called blue oil. With a treatment and distillation it is ready for its final treatment as lubricating oil. This is an outline of the course of the bulk of the oil, but at each distillation there is fractionation, and some small fractions get a greater number of distillations than I have mentioned to bring them to right gravities for the market, or to fit them for special purposes.

The treatments take place in boiler-shaped tanks of malleable iron with paddle-shaped stirrers. Air stirring, which, I believe, is most commonly used in other works, is little used in ours. As we use only the strongest sulphuric acid, and have the mineral oil thoroughly settled from water, the iron is little acted on by the acid. The acid is stirred in the oil for an hour or so, and the mixture allowed to stand until the acid combined with the basic impurities goes to the bottom as a black tar, and is run off below. The oil flows by gravitation into another stirrer, where it gets caustic soda of 60° Tw. strength (sp. gr. 1·300), and this precipitates the acid impurities, which settle to the bottom, and are run off also.

As to the quantity of acid used, we aim at giving at each stage as much acid as we can without acting on the olefines. With the proper quantity of acid given the soda tar is black, but if too much acid has been used the soda tar is a voluminous white blubbery mass. For the green oil or oil once distilled we use the vitriol tar of the final treatments to some extent, but the total treatment is equivalent to about 3 per cent, by volume of oil of vitriol. The intermediate treatments are small, but the finishing treatments are larger, and with them we designedly use acid sufficient to act slightly on the hydrocarbons, and get a white blubbery tar with

Fig. 3.

soda. We have to give sufficient acid to produce the right colour in the finished product, and when we give the right quantity we generally get the soda tar to settle out clear at once.

It is best to have the oil well refined before the final treatment, so as not to require to give much acid at this stage, for if much acid is required, although the oil may get quite bright after the soda, soda compounds are persistently retained in solution by the oil. These compounds should be easily washed out, and this should be thoroughly done. A finishing treatment, properly conducted, always lowers the gravity of the oil, but a badly conducted one sometimes increases the gravity, from the soda compounds retained. For the finishing treatment, weak caustic has to be used, or soda carbonate solution. After the washings the finished oils are put into shallow tanks, exposed to light for 24 hours, to get bright. A thing that happens sometimes, and has to be guarded against, is that, when the soda is added, a whole tank of oil may set into a solid jelly. This takes place as readily with light oil as with heavy. It would happen unexpectedly, without any apparent cause. It was some time before we discovered that if the oil was brought very slowly to the neutral point after the acid, it was sure to set. Five per cent. of soap dissolved in warm burning oil causes it to set into a jelly on cooling, so that soap can be easily made to take up and retain paraffin oil; but, with the soda compound we have to deal with, less than 0.5 per cent. is sufficient to cause the oil to set. The amount of acidity left in burning oil on settling from oil of vitriol of a finishing treatment is equal to 0.1 per cent. of SO_2 . The temperature of treatment with acid for the first treatments, particularly when much paraffin is present, may be over 100° F., but the finishing treatments are best at 60° F. or below it.

The vitriol tar is washed from sulphuric acid by agitation with hot water, and burned. It is blown into spray by a jet of steam, and the spray burns as if it were gas, giving a very high temperature, and producing little smoke. The acidity of the chimneys is practically no higher than when coals alone are burned.

Our products all belong to the two series of hydrocarbons—paraffins and olefines. Both series are represented in the permanent gas, naphtha, and burning oils, but when we come to the higher members of the series, the paraffins appear as solid paraffin, and the olefines as viscous liquids. Lubricating oil consists of olefines mixed with some liquid or low-melting paraffins. The impurities which we have to get quit of in refining have been little investigated. They are tarry substances that cannot be got to give crystalline compounds, and, on distilling, a large proportion is decomposed with formation of olefines and a little paraffin. There is a proportion of strong bases that have been partly investigated, belonging to the leucoline and the picoline series. A portion of the impurities are ready to unite with either caustic soda or sulphuric acid, and are reckoned as partly belonging to the phenol group. Except these, there are no compounds of the benzene or anthracene type. The crude oil of our retorts requires a destructive distillation to begin. If refining were started by chemical treatment, the loss would be increased, as substances are extracted which would by distillation be converted into products. Solid paraffin cannot be got from crude oil by cooling and pressing, and the paraffin exists partly in an amorphous form, and partly compounds are present which require distillation to convert them into paraffin. The paraffin, as

determined in crude oil by Engler and Boehm's method, is about 8 per cent., while in the works we get fully half as much again. Zoloziecki proved that the oxidised compounds present in petroleum were converted by distillation into paraffins, and no doubt the same is the case with crude oil.

If too much steam is passed into the crude stills, the oil distils over very little changed, and the steam has to be restrained so as to make the distillation truly a destructive one. All the distillations are to some extent destructive at the end, and too much steam is often hurtful with the heavy residues. Steam is used pretty largely for the purpose of preserving the viscosity of the heavy oil, but if overdone it only causes extra loss with the chemical treatments. When the breaking up is fairly started at the end of a distillation, volumes of permanent gas are given off which, according to Beilby and McArthur, are very rich in light-giving properties. These products of decomposition also tend to give lubricating oil a low flash point if not looked after. Even light-burning oils in distilling deposit a little coke on any solid body their vapours may come in contact with, but there is no decomposition to speak of except with the very heavy oils. From what I hear of the Americans cracking up the intermediate oils of their petroleum so as to reduce them in gravity to burning oils by manipulating the firing of the stills, I am sure that the oils they have to deal with are much more easily decomposed than ours, and Russian petroleum seems to be even more easily decomposed. Cracking up is not required by us nowadays, as there is a good market for intermediate oils of all gravities for gas making, burning in special lamps, &c. Water, on being converted into steam, increases in volume nearly 1,700 times, while burning oil increases less than 200 times, heavy oil less than 100 times, in being converted into vapour. So in distilling heavy oil without steam a great deal of oil has to be converted into vapour before it mounts up to the point of exit from the still, and as the specific heat is low it is easily condensed to fall back into the still again. The steam blown into the still is useful in preventing condensation, and in carrying the vapour over mechanically into the condensers. Two non-miscible liquids distilled together have the temperature of boiling very much lowered, sometimes a good deal below the boiling point of the lowest one; and oil distilling into vapour of water boils at a much lower temperature than when distilling into its own vapours. Some heavy residues we distil without steam, some with steam blown over the surface of the oil, and others with superheated steam blown into the bottom of the still. Solid caustic soda is put into the residue stills in the last distillation of all the heavier oils.

Steam is of great importance also for fractionation. Thorough fractionation is the great secret in oil refining. A little naphtha in burning oil lowers the flash point, of course; a little intermediate oil in it reduces the capillarity and harms the burning; intermediate oil present in lubricating oil decreases the viscosity much more than in proportion to the quantity, and so on, each kind harming the others when mixed. As a thorough fractionation cannot be made in one distillation, all advantage possible must be taken of the distillations given to make the separations required.

In regard to the separation of the solid paraffin, this is done in two stages. The heavy oil and paraffin got in the second distillation is cooled and pressed, and the expressed oil, after distillation, which helps to concentrate the solid paraffin, is again cooled and pressed. In both cases the cooling is first done

Fig. 1

by the atmosphere and then further with freezing machines. The atmospheric cooling is done either in flat tanks of a foot deep, arranged in a cool airy shed, or in long tubes of 3 ft. diameter, in which the mass is kept gently stirred by a paddle which goes the whole length of the tube. From the flat tanks the mass passes by a pipe, 1 ft. in diameter, into a stirrer, when it is broken up to be caught by a pump and thrown into the cooler to get artificial cold. In our works, for the first pressing, the refrigeration is done by ether machines, and in the second by an ammonia machine, and the cold is carried to the coolers by a brine of chloride of calcium. The coolers are tanks 10 ft. long by 6 ft. wide, of form shown in the drawing (Fig. 5). They are divided into compartments 6 ins. wide, in which the paraffin mass is put, alternating with compartments about 1 in. wide, through which the cold brine is kept flowing. In the old system of applying the cold, the refrigeration was effected suddenly—from 60° or 70° F. to 30° F. or so in a few seconds—and the solidified paraffin was partly got in an amorphous form impossible to separate completely from the oil. In the present apparatus the refrigeration is done more slowly, allowing time for the crystals to form and grow. In the first cooling the mass remains in the coolers 3½ hours, in the second eight or nine, and get cooled to 30° F. and 15° F. respectively. As the mass is a bad conductor of heat, it would take a long time to get cooled throughout if left motionless, so a scraper slowly revolves in it, constantly renewing the surface exposed to the cold. The paraffin is got in good crystalline form, in which it is easily separated from the oil. In the system Mr. Beilby described to the Society of Chemical Industry (Journ. IV., 321), the cooling is done even more slowly, requiring at the same time a proportionately larger plant. A paddle-stirrer at the bottom of the tank prepares the mass to be caught by a pump to be pressed through the filter-presses. From the filter-presses the oil runs with a setting point of 30° F. in the first cooling, and from 15° to 22° F. in the second, according to the gravity of the oil. The solid taken from the filter-presses is put into cloths and pressed in plate-presses with hydraulic ram at 30 cwt. and 20 cwt. per inch, giving hard scale and soft scale respectively. The slow method of cooling gives an extra quantity of solid paraffin and a lubricating oil improved in setting point and viscosity. Solid paraffin, when dissolved or melted, gives a thin mobile liquid deficient in viscosity, so any left in the oil, besides being a loss in itself, deteriorates the quality of the lubricating oil. Solid paraffin, when liquefied, is equal in gravity to an oil which at 60° F. is about 810 sp. gr. A heavy oil of 863 sp. gr. and setting at 42° F., after losing 10 per cent. of paraffin, has its specific gravity raised to 872, and its setting point reduced to 20° F.

All the apparatus shown in the drawings are inventions patented by Mr. Henderson, the works manager.

In refining the paraffin scale, the processes used are of three kinds: treatment with chemicals, sweating, and treatment with naphtha. If refining is wholly done with chemicals, the quantity of oil of vitriol required is large, the temperature has to be very high, the loss is great, and the refined paraffin not particularly good in colour. We use comparatively small treatments with oil of vitriol, carefully avoiding a temperature above 140° F., and this we find helpful to further refining. The soda compounds have to be very carefully washed out, otherwise they make the paraffin greasy and amorphous and difficult to refine. In the sweating process, the scale is melted and run

into shallow tins to cool. On cooling, the highest melting-point paraffins will separate first, and act as centres around which layers of lower and lower melting-point paraffins will crystallise, concentrating the colouring matters in the oil and the softest paraffins. On putting the cakes of paraffin into warm chambers, the low melting-point paraffins melt, and, along with the oil, flow out from the crystals of hard paraffin, carrying the colouring matters with them in solution. Our best refined paraffin is made by washing with naphtha. The scale is melted, and 25 or 30 per cent. of shale naphtha is stirred into it, and the mixture run into square shallow tins, where it solidifies into cakes suitable for the plate-presses. On pressing, the naphtha runs out, carrying all the colouring matter. The presses are enveloped in a thin metal hood, which is raised or lowered as required by a counterpoise weight, and this helps to prevent loss of naphtha by evaporation. Two naphtha treatments are required. The melted wax has steam blown through, to rid it of the small quantity of naphtha still retained, and after settling from water, the wax gets a small treatment with char from the prussiate works, is settled, and filtered through cloth and paper, and on cooling into blocks, is fit for the market or the candle-maker. In our busy season we make 14 or 15 tons of paraffin candles a day. Zoloziecki has some very interesting experiments on char recorded in "Dingler's Journal." His char seems to have contained much more alkali salts than the char we get in this country, with the result that our char can be recovered by distillation to be as powerful as ever, while his could not. In his case the alkali salts fused around the particles of char in the retort when recovering, which rendered it comparatively useless until washed free of alkali. We find that if the char remains too long in contact with the wax, the wax begins to take back the colouring matter to some extent.

A few words before I close regarding the properties of oils. All kinds except naphtha should have a high flash point, and should be free from acidity and from soda compounds. Oils for ordinary lamps should all distil over under 300° C. (572° F.). Light-house oil is a good example of what a burning oil should be: it distils all over under that temperature, and its flash is over 160° F. Our ordinary burning oils have a very small residue boiling above 572° F., and a flash point of about 30° above the Government safety test of 73° F. Burning oils are sent into the market in two forms, namely, distilled oils and treated oils. Distilled oils have more colour and smell, and as their refining is finished with a distillation, there should be no danger of chemicals to encrust the wick. The treated oils, if not rightly managed, may be acid in reaction and have soda compounds in solution. If acid in reaction, however pretty they may be at first, they soon get dark in colour; and when burning, the free sulphuric acid tends to char the wick for some distance under the burner. If the soda compounds are not thoroughly washed out of the oils, they cause a hard crust to form on the wick, and they often decompose in the heat of the burner, giving free sulphuric acid, and causing the wick to char. Treated oil, properly refined, burns as free from crust or acidity as a distilled oil, and the colour and smell are much better. Wicks of themselves are often acid—from the chemicals used in bleaching the cotton, I suppose. The acidity of an oil is easily tested with methyl-aniline-orange. It has to be shaken very thoroughly, and afterwards settled quite clear, before the result is certain. I have sometimes got samples of oil from ship-tanks that had been spoiled

by oxidation. The oil tank had been situated in a hot place near the engine when the oil, by the motion of the ship, had been kept shaken up with air, perhaps for months, with the result that the oil had darkened, become slightly acid, and burned badly. In ships the oil often gets contaminated with vegetable or animal oil, and a very small percentage of these causes the oil to burn very badly, or even, in a short time, to go out completely. Marine sperm used in ship lamps has a gravity of 0.830 and flash of 230° F.

In lubricating oils the flash point lies between 320° and 400° F., according to the gravity, and little should distil over under 600° F. The body or viscosity we test by passing the oil through a pipette at 60°, and noting the number of seconds required, and comparing with a standard oil. Lubricating oils, besides the ordinary form having the bloom or fluorescence characteristic of mineral oils, are sold also as bloomless oils. Dark bloomless oils are produced by oxidation with nitric acid or air, and the pale bloomless oils are made by dissolving nitro compounds in them, such as dinitrobenzol, dinitrotoluol, or nitronaphthalin. When mixed with vegetable or animal oil, the bloom generally shows itself pretty strongly again.

The paraffin oil manufacture is carried on in Scotland by 14 companies, nine of which do refining, and the production is about 60 million gallons of crude oil per annum from 2 million tons of shale, and the value of refined products about 1,500,000/. The capital invested is about 2,000,000/, and the men employed about 10,000.

DISCUSSION.

The CHAIRMAN said that all present would agree that Mr. Stenart had in his paper given a very valuable contribution, not only to the Scottish Section of the Society, but to the Society at large. Mr. Stenart had brought forward some very interesting and novel facts, the results of his own observations. Among others the actual observations on the temperatures found within a Henderson retort at various stages of the distillation, and the statements as to the distribution of the sulphur of the shale among the various products of distillation, had specially struck him. With reference to the working of the ammonia still described, perhaps Mr. Stenart would say afterwards whether there was any trouble caused by the rather complicated form of the still, seeing the liquid was not very clean. Even simpler forms of stills he knew were sometimes troublesome, unless the liquor was well settled and clean, and he would like to know what was Mr. Stenart's experience with the still in that respect.

Mr. HAMILTON said that they were very much indebted to Mr. Stenart for bringing forward a number of facts which, as the Chairman had said, were quite novel. Mr. Stenart had of course mainly referred to the operations as they were conducted at Broxburn, and had mentioned that there was little decomposition of the carbon in the Henderson retorts. That might be due to the character of the shale distilled there, but in his works they used a very much higher temperature than at Broxburn. When the spent shale was dropped from the Henderson retort into the furnace below, a very large amount of it was white or grey—showing that the steam introduced had burnt out the carbon—and possibly also increased the yield of ammonia. If the

heat were not maintained the yield of oil would be deficient. That he believed was entirely due to the character of the shale. As to continuous distillation, he could only give the result of three years' experience of it at his works, and that was that it had been most successful. At his works the stills were shut down after working a fortnight or so. He was astonished to hear that Mr. Steuart's loss by refining was only 26 per cent., as that showed a marvellous advance in finished products. To get 4 per cent. increase showed great skill and care in manipulation. In his opinion Beilby's cooler was much superior to the Henderson cooler. The crystals from the former were beautifully formed, whereas from the latter only a considerable amount of previous coolings gave any crystals at all worth speaking of. In the Henderson cooler at his works they had been told to leave the stirrer quiet until the bulk of the oil cooled. They tried it once, but not again, as they had simply to melt the oil up again.

Mr. D. A. SUTHERLAND said it was hardly necessary for him to say more on the subject, as Mr. Steuart had so exhaustively dealt with it. There was one point, however, to which his attention had been drawn by Mr. Hamilton's remarks. Mr. Hamilton spoke of finding the spent shale white on being dropped from the retort into the combustion chamber. He had occasionally noticed the same thing in the works with which he was connected, viz., those of the Burntisland Oil Company, Limited. He had usually found that this was due to too great a suction, or that the doors were imperfectly locked, in either case air being drawn in. Further, Mr. Hamilton had obtained a higher yield of oil by using a higher heat; his own experience, founded on a number of experiments, was that by the application of a strong heat more ammonia, but less oil, was obtained. There was, of course, an intermediate heat at which the most advantageous yield of both could be obtained. If the heat was high he had found the specific gravity increase to .880 or higher. He might as well mention, as being of interest, with reference to the quality of shale, that the yield of Burntisland shale corresponded closely with that mentioned as obtained at Broxburn, having a specific gravity of .865, and a setting point of 80° F. Mr. Steuart spoke of solidifying burning oil with 5 per cent. of soap; he would add that he had gelatinised lubricating oil with about .5 per cent. The thickened oil referred to as occurring occasionally in the process of refining seemed, as a rule, to be caused by over-treatment with acid, and was formed in the subsequent washing with soda; it was known as "glut," and was a splendid detergent. It might be of interest to some members to know, what, of course, would be familiar to Mr. Steuart, that this glut could usually be cut down by agitation with a saturated solution of common salt.

Mr. HAMILTON said that he should like to add that the specific gravity of their crude oil never exceeded .864.

Mr. STEVENSON would like to make one remark concerning the dissolving of the soap. It was found that it required a pretty large percentage of soap to make lubricating oil set; experiment showed that 2½ per cent. was not sufficient, and that 5 per cent. was required, so that this substance which was in the oil, and which produced the jelly, was something of a far better nature than an ordinary soap.

Mr. SUTHERLAND: Was any other medium used?

Mr. STEVENSON : No.

Mr. SUTHERLAND : In the case I refer to methylated spirit was used.

The CHAIRMAN had understood that the soap must be dry.

Mr. HAMILTON had understood the same.

Mr. W. HUME said he would like to ask a question with regard to the minimum melting point of solid paraffins, and also regarding the transparency of the paraffins. In the Glasgow Exhibition he saw a case containing paraffin of this transparent nature, and he would like to know if any special treatment was required to make it thus.

Mr. HAMILTON said that it might be interesting to mention that within the last month or so he had been trying sulphated olefines (or "white water," as he called it) in one or two paper works. They had been in the habit of using paraffin oil, but it used to leave specks on the paper; but this "white water" not only left no specks but also effected a saving in bleaching powder. He was now having it tried in yarn bleaching works, and, so far as he could learn, it was likely to prove an equal success.

Mr. TATLOCK said that Mr. Stewart's remarks with regard to paraffin wax had attracted his attention. During the references to the specific gravities and melting points of certain paraffins, it occurred to him that a paraffin or mixture of paraffins of constant specific gravity and melting point might be employed as a standard of light. The candle commonly used for that purpose was of a very uncertain composition and of varying luminosity—though it might burn at a fixed rate in a given time. He would like to ask Mr. Stewart whether a mixture of paraffins of certain melting point and specific gravity would be likely to burn with constant luminosity other conditions being equal. He should also like to ask whether the effect of moderate pressure on paraffin was to increase its specific gravity. His experience had been that it did.

Professor DITTMAR said that the melting point of paraffin rose when the pressure rose. Hence, supposing a paraffin, after having been fused, to be cooled down to its natural fusing point, there were two means for causing solidification, and thereby formation of an amorphous cake. They might either suddenly lower the temperature at ordinary pressure, or maintain the temperature and raise the pressure to say 10 or 20 atmospheres.

Mr. STEWART, in reply, said, that while the several gentlemen were speaking, many things occurred to him that he might speak about, but he did not know whether he could now recollect them all. As to the ammonia column still, if it should happen to choke, the obstruction was easily got at from the side doors and removed, so that there was very little trouble from this cause. The stills were cleaned out once a year. He had never noticed the whitening of the shale, attributed to the steam acting on the coke, although the spent shale was sometimes left in the retort some hours beyond the usual time in order to increase the yield of ammonia. Where it had happened he suspected that air had been sucked in. Mr. Hamilton was surprised at their increase in refined products during the year. He had not the figures with him, but there was no doubt that the amount of loss had been gradually reduced from year to year. Last year it would be about 27 per cent.

if he remembered rightly. Regarding the cooler, Mr. Henderson originally intended that the paraffin should remain at rest during cooling, and that the stirrer should only be put on at the end to bring it down, but the difficulty was to get the stirrer to move. It was found that by sending it slowly round all the time a paraffin was got that separated quite readily from the oil, and gave an oil of sufficiently low setting point. Of course, the more rapidly the cooling took place the more economically it could be carried out. In regard to the amount of steam used in residue stills he, of course, had gone into that pretty fully in his paper. But it was found, in the case of green oil residue, that if a great amount of steam was passed into the still the paraffin scale extracted from the distillate was green and difficult to refine, and that no extra loss was incurred by restricting the steam according to the circumstances of the case. It was also asked what was the minimum melting point of paraffin. It could be got in quantities about 80° F., but the difficulty was in finding a market for such very low melting points. A question had been asked as to whether there was any special treatment required to make the paraffin transparent, as was the case with some shown at the Glasgow Exhibition. Paraffin wax was no doubt in itself transparent, but in its ordinary state it appeared opaque from the substance existing in the form of small crystals, with free spaces between. When gently warmed paraffin became plastic, and when pressed in this state the interspaces were done away with, and the mass became transparent, like glass. The interspaces being reduced by pressure was no doubt also the explanation of the increase in specific gravity which Mr. Tatlock had remarked.

Regarding Mr. Tatlock's remarks as to getting a constant luminosity, he had no doubt that paraffin could be made of such a homogeneous structure that it would be practicable to get a constant luminosity; but the matter of wick entered considerably into the question as to whether a constant light could be got from the candles or not, but he had not made any experiments on the subject.

Ad libitum.

I find that up till 1885 our total loss in refining was 30 per cent. on the crude oil, but much lower ever since. The cost of refining in 1879 was 1.38*d.* per gallon of crude oil. For the last nine months it has averaged 0.77*d.*

In regard to retorts, I neglected to state that the total fuel required for breaking the shale, raising steam, haulage, pumping, and everything else connected with the crude oil, was 1 cwt. coals per ton of shale.

We cannot put caustic soda into the boiler stills, but it can always be put into the residue stills, which are the last of each series.—D. R. S.

Journal and Patent* Literature.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Improvements in Machines with Spiked Appliances for Reducing or Pulverising Superphosphates and other Materials. H. D. Salomonson and J. Laubheimer, Kralingshe Veer, Holland. Eng. Pat. 17,094, December 12, 1887. 8d.

THE essential features are a spiked roller in combination with a roller reciprocating on its axis, so that the spikes of the one "take in" between those of the other and keep them clear.—J. M. H. M.

Improvements in Pumps for Gases and Vapours. M. C. Bannister, Liscaud. Eng. Pat. 17,430, December 19, 1887. 8d.

THE invention relates to improvements in the valves and pistons of air-pumps such as are used in connexion with ice-making machinery, also to a method of transferring motion from one piston to one or more others by means of an enclosed body of water, for the purpose of avoiding waste in the cylinder passages, and in the power required for working such pumps. For particulars the specification and patent drawing should be consulted.—B.

An Improvement in Filters. R. Morris, Blackheath. Eng. Pat. 211, January 5, 1888. 8d.

THE improved filter is constructed so as to secure a zigzag path for the liquid through the filtering material, which

* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Rander Luck, Controller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.	½d.
Above 8d., and not exceeding 18. 6d.	1d.
" 18. 6d. " " 28. 6d.	1½d.
" 28. 6d. " " 38. 6d.	2d.

occupies annular spaces between partitions projecting upwards from a basin below and alternate with partitions projecting downwards from a vessel inverted above.

—C. C. H.

Improvements in the Construction of Filters, mainly designed for the Filtration of Water for Manufacturing Purposes, but applicable generally to the Filtration of Water in Quantities. W. A. Nicholl, Sowerby Bridge. Eng. Pat. 606, January 14, 1888. 8d.

A TANK or cistern is divided into three parts by two diaphragms, one of which is perforated at the bottom, and the other at the top; between the two the filtering material is packed, coarse material, e.g., broken bricks, pebbles, &c. at the bottom, and finer material, e.g., charcoal, at the top. The water enters the end compartments and flows through the perforations at the bottom of the first partition, ascends through the bed of filtering material, overflowing into the receiving portion of the tank through the holes in the upper part of the second diaphragm.—C. C. H.

Improvements in Means or Apparatus for subjecting Substances or Articles to the Action of Air or Gases for effecting the Drying, Disinfecting, Oxygenating, or other Treatment thereof. H. J. Peck, London. From H. G. Downton, Sydney, New South Wales. Eng. Pat. 2057, February 10, 1888. 8d.

THE substance with which the air is to be charged or dried is placed on a perforated floor in a chamber with a bell-mouthed cover communicating by means of a pipe, which may pass through a boiler flue when the air is to be heated, with the bottom of a chamber having a perforated floor, on which the material to be treated is placed. A bell-mouthed pipe from the highest part of the reception chamber passes to an air ejector worked by steam, thus ensuring the passage of a good current of air through the system described; the air may be passed through the furnace of the steam boiler to destroy any noxious vapour, &c. removed from the substances treated.—C. C. H.

An Improved Method of Filtering and Apparatus therefor. H. F. Clayton and G. H. Holdroyd, Huddersfield. Eng. Pat. 13,936, September 27, 1888. 6d.

THE apparatus is shown in adjoining figures. The water is forced into the pipe E by pump L, and rising through the

filtering bed K, with which the cylinder D is packed, enters the perforated cylinders A, which are each covered with a filter cloth, through which it passes, and is collected in cistern R.—C. C. H.

II.—FUEL, GAS, AND LIGHT.

Discovery of Natural Gas Wells at Narrabeen, near Sydney, New South Wales. Sydney Daily Telegraph, Nov. 28, 1888.

WHILST boring for coal in the neighbourhood of Narrabeen, about seven miles from Manly Beach, a party of miners, working for Mr. John Coghlan, have tapped a reservoir of natural gas. Since natural gas is almost always found in conjunction with petroleum at various depths in the earth, great expectations have been raised by the discovery. Mr. Coghlan had put down his diamond drill amongst the picturesque scenery in the midst of which Mr. van Bieren had previously tried in vain to procure wood suitable for the charcoal used in the manufacture of gunpowder. It is not far from the lagoon, about half-way between Manly and Newport, and at the foot of a range of hills. It is "poor" country, covered with out-cropping rock and barely clothed with impoverished gum-trees. Beneath the surface, to unproved depths, the strata are composed of sandstone and conglomerate. After boring for two or three years, probing 1,556 feet down, and finding no trace of coal, the miners observed an inflammable vapour issuing from the side of the bore. Mistaking it for marsh gas, and never dreaming of the existence of natural gas in Australia, they paid no attention to it, and proceeded to go deeper and deeper into the rock.

At length, with nearly 2,000 ft. of tubing down, the vapour increased in volume and intensity. Then Mr. Coghlan invited Dr. Storer, a chemist, and Mr. Key, a mining engineer, to inspect the bore. These gentlemen visited the scene of operations, and offered the opinion that the gas was similar to that discovered at Pittsburg, in America, in all respects. The bore measured 3 ins. in diameter, and the gas issued through it in spite of a pressure of water equal to 800 lbs. to the square inch. It is proposed to form a company and lay service pipes to Sydney, using the raw gas for fuel, and mixing coal gas with the rest, for illuminating purposes.

Natural gas is rarely if ever found in the immediate neighbourhood of coal, i.e., it is not actually found in conjunction with coal. As far back as 1842, Prof. Beek traced its connexion with bituminous matter other than coal, and with petroleum, which he said was generally diffused through the strata of sandstone and slate in the same localities.—W. S.

PATENTS.

Treatment of Air, Gases, Liquids, and Furnace Chimney Products. H. J. Wilson and J. W. Wilson, Sheffield; and A. French, Lead Hills. Eng. Pat. 5239, December 21, 1878. Second Edition. 11d.

HEREIN is described a process for bringing any gas into intimate contact with water or some other washing liquid. It consists in distributing the said gas in numerous small streams beneath wire gauze or other permeable screens submerged in suitable liquid. To secure the greatest efficiency the interstices of the screens must be greater than the solid particles to be removed from the gas, so that no clogging or choking can occur, and the liquid carried mechanically upward through the screens must be provided with separate unimpeded passages for its return. Full drawings are appended to the specification.—A. R. D.

Improvements in Apparatus for Generating Gas. H. Hutchinson, London. Eng. Pat. 17,799, December 27, 1887. 8d.

At the bottom of a generator of the ordinary cupola type is a steam air-injector, the upper or delivery end of which

is surmounted by a cap of iron or fire-clay. This cap is perforated round its base and forms a superheater, as the mingled air and steam have to pass in contact with its inner surface before escaping through the perforations into the mass of superjacent fuel. In addition to this, four pipes from the central blower deliver air and steam to the outer parts of the fuel in the generator. Provision is made for injecting liquid hydrocarbon into the lower part of the generator, if desired, and the apparatus includes a "hydrocarbon converter" or fixing chamber, where the mixed gases are rendered permanent by contact with heated brick or other material.—A. R. D.

Improvements in Apparatus to be used in the Purification of Coal Gas. W. T. Walker, London. Eng. Pat. 14,925, October 17, 1888. 8d.

THE gas is made to pass in contact with a number of wetted surfaces, as in Eng. Pat. 1478 of 1880. The surfaces are contained in boxes open at the bottom and at each end, and these boxes are attached to a shaft having a reciprocating vertical motion, so that at each downward movement they are completely submerged in any suitable liquid. The operation is carried on in a number of tanks placed one above the other, and of which each is isolated from its neighbours by a water-tight seal. The specification is accompanied by detailed drawings.—A. R. D.

An Improved Method of Solidifying Petroleum and other Explosive Oils for Safer Transport, as well as a Fuel for Cooking, Lighting, and Heating. H. O. A. E. Grünbaum, London. Eng. Pat. 15,492, October 27, 1888. 4d.

It is proposed to solidify petroleum by the admixture of glutinous or gelatinous matter, such as fish-glue. With this may be incorporated any kind of finely divided combustible, and the whole compressed into any suitable form.—A. R. D.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

PATENT.

Improvements in and Relating to the Treatment of the Acid Residua or Tars resulting from the Refining of Mineral Oils by Concentrated Acids. C. Rave, Malines, Belgium. Eng. Pat. 607, January 14, 1888. 6d.

THE (sulphuric) acid tars, generally, are treated with iron turnings and water. Sulphate of iron is formed and removed by repeated washings. The residue is freed from water by heating, concentrated to any desired consistency, and thus transformed into a neutral bitumen, having all the properties of natural bitumen. The very fluid acid tar, formed by purifying naphtha with sulphuric acid, gives off large quantities of sulphurous acid when heated. This is utilised for preparing sulphites and bisulphites. Neutral tars treated with sulphuric acid yield hydrocarbon oils and acid tars, which latter are decomposed with iron turnings, as above. The bitumens so obtained are well adapted for asphalt making, and have various other industrial applications.—A. R. D.

IV.—COLOURING MATTERS AND DYES.

On some Derivatives of Anthraquinone. A. G. Perkin and W. H. Perkin, jun. J. Chem. Soc. 1888, 831—844.

SODIUM anthraquinone monosulphonate, when submitted to destructive distillation, gives a brownish-red distillate,

containing *m*-oxyanthraquinone, anthraquinone, and a new substance crystallising from glacial acetic acid in small orange-red needles, having the composition $C_{28}H_{11}O_6$. This is insoluble in alkalis, and gives with zinc dust and caustic soda solution the anthraquinone reaction. By fusion with potassium hydrate it is converted into alizarin. Nordhausen sulphuric acid at 190° C. forms with it two sulphonic acids, the mixed sodium salts of which, fused with potassium hydrate, produce a mixture of anthrapurpurin and flavopurpurin.

Heated with hydriodic acid in a sealed tube, it is converted into anthraquinone and dihydroanthracene, but if hydriodic acid is gradually added to a hot solution of the substance in glacial acetic acid a yellow crystalline product of the formula $C_{28}H_{11}O_5$ is formed.

Chromic acid acts energetically on a solution of $C_{28}H_{11}O_6$ in glacial acetic acid, producing a white crystalline substance having the formula $C_{11}H_6O_3$, which is converted by fusion with potassium hydrate into alizarin and anthraquinone. This $C_{11}H_6O_3$ forms, with Nordhausen sulphuric acid at 190° C., two sulphonic acids, the sodium salts of which, when separated, give on fusion with potassium hydrate, respectively, flavopurpurin and anthrapurpurin.

The orange red substance, $C_{28}H_{11}O_6$, dissolves in cold fuming nitric acid, producing a substance having the composition $C_{28}H_{11}O_7$, which crystallises from a mixture of aniline and alcohol in minute colourless needles. Fusion with potassium hydrate also converts this into alizarin, but at the same time reduction takes place, a portion being reconverted into $C_{28}H_{11}O_6$. With Nordhausen sulphuric acid a mixture of two sulphonic acids are obtained, the sodium salts by fusion with potassium hydrate giving a mixture of anthrapurpurin and flavopurpurin. Chromic acid in glacial acetic acid solution converts $C_{28}H_{11}O_6$ into the substance $C_{11}H_6O_3$, described above.

A boiling mixture of nitric acid and sulphuric acid acts on $C_{28}H_{11}O_6$ with the formation of a nitro-compound, very similar in its properties to dinitro-anthraquinone, with which, however, it is not identical.

From a study of these properties the authors assign the following constitutional formulae to the substance $C_{28}H_{11}O_6$, and its derivatives:—

Penta-ethylbenzene. O. Jacobsen. Ber. **21**, 2814—2819.

PENTA-ETHYLBENZENE is prepared by the action of aluminium chloride and ethyl bromide upon benzene. 160 grms. of the purified product are added gradually to 500 grms. of

chlorosulphonic acid and the resulting paste is mixed with snow and filtered. This consists mainly of the sulphochloride and sulphone of penta-ethylbenzene. The former, by digesting with alcoholic caustic soda, is converted into the sodium sulphonate, which crystallises on cooling. The sulphone is obtained from the alcoholic mother-liquor by evaporation and extraction with water.

Penta-ethylbenzene is a viscous oil, boiling at 277°. The sulphone is a crystalline body, melting at 76°. The author has prepared a series of salts of penta-ethylbenzene sulphonic acid.

Action of Sulphuric Acid on Penta-ethylbenzene.—Fuming sulphuric acid at 120° converts penta-ethylbenzene into a solid resinous body, which consists mainly of hexa-ethylbenzene. The penta-ethyl compound is mixed with an equal volume of ordinary sulphuric acid, and then sufficient fuming acid added to form a clear solution. The mixture is allowed to stand 4–5 days, until no more of the hexa-ethylbenzene separates, when it is filtered, washed, and crystallised from alcohol containing toluene. In the filtrate the sulphonic acid of tetra-ethylbenzene is contained. Hexa-ethylbenzene is a solid body, melting at 129°.—J. B. C.

Tetra-ethylbenzene. O. Jacobsen. Ber. **21**, 2819—2821.

ON sulphonating tetra-ethylbenzene with chlorosulphonic acid (the hydrocarbon being obtained by the action of ethyl bromide and aluminium chloride on benzene) a mixture of adjacent and symmetric tetra-ethylsulphonates are obtained. Apparently the third unsymmetric sulphonate is also present. If the crude mixture of the tetra-ethylbenzene be dissolved in ice-cold chlorosulphonic acid, and the solution exposed to the air at 0° and finally diluted with the addition of ice, an oily layer separates, which consists of sulphones and chlorosulphonic acids. These may be separated with ether, and on distilling off the latter and digesting with alcoholic soda solution the sodium salts of the sulphonic acids are formed, from which the sulphones may be extracted with petroleum spirit. The different sulphonic acids may be separated by fractional crystallisation of the sodium or barium salts.—J. B. C.

Synthesis of Prehnitene (Tetramethylbenzene).

O. Jacobsen. Ber. **21**, 2821—2828.

PREHNITENE may be obtained not only by the action of sulphuric acid on penta-methylbenzene or durene, but also from adjacent bromopseudocumene and dibromometaxylene by Fittig's synthesis.

Bromopseudocumene, $C_6H_2CH_3 \cdot CH_3 \cdot CH_3 \cdot Br$, [1:3:4:2] is the liquid product of the bromination of pseudocumene, 1 kilo. of pure pseudocumene yields 320 grms. of the crude adjacent bromopseudocumene. The author has prepared a series of derivatives from this body. 25 grms. of the pure compound, when heated with 40 grms. of methyl iodide and 14 grms. of sodium in thin flakes in presence of the necessary quantity of ether, yield a product boiling at 200–204° which is nearly pure prehnitene. The author points out the interesting fact that symmetric bromopseudocumene may be converted into the adjacent modification by the action of fuming sulphuric acid, which yields adjacent bromopseudocumene sulphonic acid.

Dibromometaxylene [1:3:4:5]. This body is the liquid product of the bromination of metaxylene. That it has the constitution $C_6H_2 \cdot CH_3 \cdot CH_3 \cdot Br \cdot Br$ [1:3:4:5] has been shown by the author by preparing from it orthodiamidometaxylene. Prehnitene is prepared from the dibromocompound in the manner described under that from pseudocumene. As in the case of bromopseudocumene, symmetric dibromoxylene may be converted by strong sulphuric acid at 230°–240° into the adjacent compound.

—J. B. C.

Adjacent Metaxylenol. O. Jacobsen. Ber. 21, 2828—2829.

The author has prepared metaxylenol from *p*-oxymesitylenic acid by heating with hydrochloric acid. The melting point, 47°—48°, agrees with that observed by Nölting, who obtained the same body from metaxylidine.—J. B. C.

Metadiethylbenzene. A. Voswinkel. Ber. 21, 2829—2831.

The author prepared this body by the action of ethyl bromide and aluminium chloride on benzene. It may be separated from the para-compound formed at the same time, by converting the hydrocarbon into the sulphonic acid and the acid into the barium salt. The barium salt of the para-compound is much more soluble than that of the meta-derivative. It is purified by converting the sulphonic acid into the amido-compound and decomposing the latter with hydrochloric acid. It boils at 181—182°, and does not solidify at 20°. The author has prepared a series of derivatives of the hydrocarbon.—J. B. C.

Stilbene. L. Aronstein and A. F. Holleman. Ber. 21, 2831—2834.

ACCORDING to Wislicenus' theory, there must be two geometrically isomeric stilbenes, and it seems possible to pass from one to the other according to the following scheme:—

This, on removing HBr and replacing the other Br atom by H, should yield—

or vice versa.

The authors find that by the reduction of monobromostilbene either with sodium amalgam or zinc dust and glacial acetic acid the original product is obtained. Zinc dust and alcohol acts similarly. An attempt to prepare the isomeric stilbene by the reduction of tolane with sodium and methyl alcohol yielded ordinary stilbene. The authors have, however, obtained an oil by the action of alcoholic potash on monobromodibenzyl, which they consider may turn out to be the isomer in question.—J. B. C.

On the Azoxylenes, Diamidodixylyls and Colouring Derivatives of the latter. E. Nölting and T. Strieker. Ber. 21, 3138—3149.

THE authors prepared the hitherto unknown azoxylenes from the five isomeric nitroxylenes (perfectly pure). The reduction was carried out in alcoholic solution with caustic soda and zinc dust; in some cases, however, sodium amalgam was preferred. The hydrazo-compounds were either obtained by using a larger amount of the reducing agent, or from the azo-compounds by means of sulphuretted hydrogen in an alcoholic solution of ammonia. The zinc dust which was used contained 90 per cent. of metallic zinc.

Adjacent Azo-orthoxylenes—

20 grms. of *o*-nitroxylenes, 20 grms. of caustic soda solution (containing 32 per cent. of NaOH), and 100 cc. of alcohol, are heated at the reversed condenser, 20 grms. of zinc dust being gradually added. The reaction is completed in about

an hour. After filtration and partial evaporation of the alcohol, crystals are obtained, which are treated with dilute hydrochloric acid to get rid of any hydrazo-compound. After several recrystallisations from alcohol, orange-yellow needles are obtained, easily soluble in alcohol, ether, benzene, and melting at 110°—111° C.

Adjacent Hydrazo-orthoxylenes was prepared from the azo-compound by sulphuretted hydrogen. It forms needles, melting at 139°—141° C. and is easily oxidised in the air.

Unsymmetric Azo-orthoxylenes—

To prepare this body it is essential to use more alcohol and less caustic soda than in the preceding case, else the formation of a red body takes place, which is probably a stilbene derivative. This azo-orthoxylenes is more difficultly soluble in alcohol than its isomer; it forms red needles, melting at 140°—141° C. Its hydrazo-compound is obtained in the manner already described. Yellowish-white needles, melting at 106°—107° C.

Unsymmetric Azometaxylenes—

It is best prepared from 25 grms. of nitrometaxylenes, 25—30 grms. of zinc dust, 15 grms. of caustic soda solution, and 300 cc. of alcohol. The azo-compound forms red needles, melting at 129° C.

Its hydrazo-compound is best prepared from the nitroxylenes, by using the following proportions:—30 grms. of nitroxylenes, 30 grms. of caustic soda solution, 40 grms. of zinc dust, and 250 grms. of alcohol. Beautiful white needles, melting at 120°—122° C.

Symmetric azometaxylenes—

10 grms. of symmetric nitrometaxylenes, 10 grms. of caustic soda solution, 10 grms. of zinc dust, and 60 cc. of alcohol, are used. Orange needles, melting at 136°—137° C.

Its hydrazo-compound forms white needles, melting at 124°—125° C.

Azo-paraxylenes—

is prepared by using 20 grms. of nitroparaxylenes, 16 grms. of caustic soda solution, 16—20 grms. of zinc dust, and 200 cc. of alcohol. Yellow needles, melting at 119° C.; probably identical with Werigo's azoxyxylenes (melting at 120° C.)

Its hydrazo-compound forms white needles, melting at 145°, and is best prepared by using 30 grms. of nitroparaxylenes, 25 grms. of caustic soda solution, 45 grms. of zinc dust, and 250 cc. of alcohol.

To prepare the diamidodixylyls, the hydrazoxylenes are heated either dry or in alcoholic solution with moderately dilute hydrochloric acid. The solution is then rendered alkaline, the base extracted with ether, and the hydrochlorides precipitated with gaseous hydrochloric acid. The hydrazo-compound corresponding to the unsymmetric nitrometaxylenes forms, however, mostly azoxyxylenes and xylidines. The latter is removed from the diamidodixylyl by distillation with steam. The hydrazo-compound obtained from the unsymmetric nitro-orthoxylenes did not yield any diamidodixylyl by the above treatment with hydrochloric acid. Schultz's method, treating the azoxyxylenes with stannous chloride and hydrochloric acid, produced the desired result.

Stilbene Derivatives from asymmetric-nitro-ortho- and nitro-metaxylenes.—Klinger obtained from *p*-nitrotoluene and alcoholic caustic soda a red condensation product, which, when treated with tin protochloride and hydrochloric acid, was converted into diamidostilbene. In the same way the nitroxylenes, in which the nitro-group is in the para position to a CH₃ group, yield red [nitro-orthoxylenes] or brownish-red [nitrometaxylenes] condensation products, nearly insoluble in all ordinary solvents. By treating the former with stannous

chloride and hydrochloric acid a base is obtained which is doubtless diamidodimethylstilbene. All these bases, diphenyl and stilbene derivatives, yield when diazotised and combined with certain phenols or amines colouring matters, which dye vegetable fibres without mordant. The authors have also prepared the tolidines from *p*- and *m*-nitrotoluenes.

The following table contains the results compared with those obtained from benzidine, tolidine, and diamidostilbene.

The following colours were obtained by diazotising the bases named in the first column, and combining them with the compounds named in the second, third, and fourth columns.

	Naphthionic Acid.	α -Naphthol α -sulphonic Acid.	β -Naphtholdisulphonic Acid R.
Benzidine $\text{NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{C}_6\text{H}_4\cdot\text{NH}_2$ [1:1 and 1:1].	Red [yellowish Congo.]	Blue violet.	Blue violet.
Tolidine from <i>o</i> -nitrotoluene $\text{NH}_2(\text{CH}_3)\text{C}_6\text{H}_4\cdot\text{C}_6\text{H}_4(\text{CH}_3)\text{NH}_2$ [1:3:1 and 1:3:1].	Red bluish Benzopurpurin.	Blue violet, but not so blue as the above.
Tolidine from <i>m</i> -nitrotoluene [4:2:1 and 1:2:4].	Red [yellowish]. Does not dye well.	Claret red. Dyes well.	Bluish red. Dyes well.
Tolidine from <i>p</i> -nitrotoluene [6:3:1 and 1:3:6].	Red [yellowish]. Dyes badly.	Bluish red. Dyes badly.	Bluish red. Dyes very badly.
Diamidodixyl from [1:2:3 nitro-ortho]xylene $\text{NH}_2(\text{CH}_3)_2\text{C}_6\text{H}_3\cdot\text{C}_6\text{H}_3(\text{CH}_3)_2\text{NH}_2$ [1:3:2:1 and 1:2:3:4].	Orange red. Dyes well.	Bluish red. Dyes well.	Bluish red. Dyes badly.
Diamidodixyl from [1:2:4 nitro-ortho]xylene [6:4:1:3 and 1:3:4:6].	Yellowish red. Dyes badly.	Bluish red. Dyes badly.	Bluish red. Dyes badly.
Diamidodixyl from [1:3:4 nitro-meta]xylene [6:5:3:1 and 1:3:5:6].	Yellowish red. Dyes badly.	Orange red. Dyes well.	Red. Dyes badly.
Diamidodixyl from [1:3:5 nitro-meta]xylene [1:6:2:1 and 1:2:6:4].	Yellowish red. Dyes well.	Yellowish red. Dyes well.	Red. Dyes badly.
Diamidodixyl from [1:4:2 nitro-para]xylene [4:5:2:1 and 1:2:5:4].	Very bluish red. Dyes badly.	Violet. Dyes badly.	Violet. Dyes badly.
Diamidostilbene $\text{NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{C}_2\text{H}_2\cdot\text{C}_6\text{H}_4\cdot\text{NH}_2$ [1:1 and 1:1].	Red.	Blue.	Blue.
Dimethyldiamidostilbene from [1:2:4 nitro-ortho]xylene $\text{CH}_3(\text{NH}_2)\cdot\text{C}_6\text{H}_3\cdot\text{C}_2\text{H}_2\cdot\text{C}_6\text{H}_3(\text{NH}_2)\text{CH}_3$ [6:4:1 and 1:4:6].	Violet. Dyes well.

—A. L.

On the Adjacent Metaxyldine and its identity with Wroblewsky's Orthoxyldine. E. Nölting and B. Pick. Ber. 21, 3150—3154.

NÖLTING and PICK proved some years ago that on nitration of metaxylylene besides asymmetric nitrometaxylylene adjacent nitro-metaxylylene is also formed (compare this Journal, 1886, 27 and 28). The commercial xylydine must therefore contain it. To isolate it, xylydine is converted into its sulphate; this is allowed to crystallise and from the mother-liquor the base is liberated by alkali. This is distilled and the part boiling from 212°—216° is converted by acetic anhydride into the acetyl compound. The *v*-meta-acetylyldide is not attacked by boiling dilute sulphuric acid containing 25 per cent. of H_2SO_4 , whilst its isomers are decomposed. The crude acetyl compound is therefore boiled with four times its weight of 25 per cent. sulphuric acid for several hours, and on cooling the *v*-meta-acetylyldide crystallises out. After recrystallisation from hot water it

melts at 176° C. It is decomposed into *v*-metaxylydine by heating with three parts of 70 per cent. sulphuric acid to 200° C. for some time.

The hydrochloride, nitrate and sulphate of *v*-metaxylydine were prepared and analysed.

Some years ago Wroblewsky described a xylydine, which he at first considered as α , and later as *v* orthoxylydine. But according to its properties it is neither one nor the other, but impure *v*-metaxylydine. Its acetyl compound, which probably was impure, was said to melt at 131°, but the properties of the salts were identical with those of *v*-metaxylydine.

The authors prepared some salts of the orthoxylydines, and estimated their solubility.

The ortho-metaxylydine is distinguished from the others by the great solubility of its sulphate, by the difficulty with which it is acetylated, by the high melting point and the difficult saponification of its acetyl compound.

	<i>v</i> -Orthoxylydine.	Asymmetric orthoxylydine	<i>v</i> -Metaxylydine.	Wroblewsky's so-called Orthoxylydine.
Hydrochloride.....	+ 1 H_2O	+ 1 H_2O	+ $\frac{1}{2}$ H_2O needles	+ $\frac{1}{2}$ H_2O

The xylol prepared from the base in the ordinary way forms white needle, melting at 48°C ., difficultly soluble in water, easily in alcohol, ether, &c.—A. L.

On Orthonitroanilinesulphonic Acid and some of its Derivatives. R. Nietzki and Z. Lerch. Ber. **21**, 3220—3223.

If acetyl sulphanilic acid be treated with nitric acid, *o*-nitrosulphanilic acid is obtained, which is probably identical with the one described by Goslich. To prepare this compound one part of acetanilide is dissolved on the water-bath in 2—3 parts of sulphuric acid containing 18—20 per cent. of sulphuric anhydride, then two parts of sulphuric acid are added, and a mixture of the required amount of nitric acid with an equal volume of sulphuric acid gradually dropped in. The mass is poured on to ice and the free nitrosulphanilic acid separates in yellowish needles. It is very soluble in water, difficultly in dilute sulphuric acid and concentrated hydrochloric acid. On boiling for some time with caustic potash, ammonia is given off and nitrophenolsulphonic acid formed. If an aqueous solution of the nitrosulphanilic acid be treated with hydrochloric acid and sodium nitrite, light yellow needles of nitrodiazobenzenesulphonic acid separate out of the solution. On reduction with stannous chloride and hydrochloric acid this compound forms a hydrazine. With phenols colouring matters are formed. On heating *o*-nitrosulphanilic acid with tin protochloride and hydrochloric acid, *o*-phenyldiaminesulphonic acid is formed, the hydrochloride of which separates out of the solution in small colourless needles. This salt is very easily decomposed, and after several recrystallisations from water the free sulphonic acid is obtained. On exposure to air its colour changes to a greenish blue. Ferric chloride produces in its solution a red-brown colouration, but no crystals are precipitated, as is the case with *o*-phenyldiamine. It forms combinations with orthoquinones as with erconic and rhodizonic acids.

If *o*-nitrodiazobenzenesulphonic acid be added to a well-cooled strongly acid solution of tin protochloride, small light-yellow needles of the corresponding hydrazine are formed. It is more difficultly soluble in cold than in hot water, but is decomposed by continuous boiling. It dissolves in caustic alkalis and carbonates with a reddish-brown colour. It yields a tartrazine colour with dihydroxytartaric acid. By treating with an acid solution of tin protochloride and an excess of tin, nitrohydrazinesulphonic acid is converted into the amidehydrazinesulphonic acid. It is remarkable that the latter is not capable of producing a tartrazine colour with dihydroxytartaric acid.—A. L.

On α -Naphtholbidiazobenzene and α -Naphthylaminebidiazobenzene. C. Krohn. Ber. **21**, 3240—3242.

Two molecules of diazobenzene chloride are gradually added to an alkaline solution of one molecule of α -naphthol. After 12 hours standing a brownish-black powder is precipitated, which is boiled with caustic soda, to remove mono azo- α -naphthol. It is then crystallised from aniline. It melts at 183°C ., is soluble in chloroform, ether, benzene difficultly soluble in petroleum spirit, alcohol, and glacial acetic acid. On reduction with tin and hydrochloric acid, it is converted into aniline and diamido- α -naphthol. Its constitution is therefore:— $\text{C}_{10}\text{H}_5(\text{OH})(\text{N}:\text{N}.\text{C}_6\text{H}_5)_2$ [1:2:4].

The preparation of α -naphthylaminebidiazobenzene is more difficult than that of α -naphtholbidiazobenzene. It is impossible to obtain it in alkaline or neutral solution. If, however, one molecule of diazobenzenechloride be added to one molecule of naphthylaminemonazobenzene, dissolved in alcohol and containing sodium acetate, the colour of the solution is changed from red to brown; after 12 hours standing the reaction is finished. α -naphthylaminebidiazobenzene is difficultly soluble in most solvents, easily in chloroform. It crystallises from aniline in red needles, melting at 189° . It forms salts, which are decomposed by water. Its acetyl compound melts at 265°C . On reduction with tin and hydrochloric acid, aniline and triamidonaphthalene are formed, the latter of which forms

with phenanthrenequinone an azine. There is, therefore, in the original compound one azo-group in the ortho position to an amido-group and its constitution is—

Action of Sulphuric Acid on α -Nitronaphthalene. W. Palmaer. Ber. **21**, 3260—3264.

According to Clève the chief product obtained by the action of sulphuric acid on α -nitronaphthalene is α -nitronaphthalene sulphonic acid. The present paper treats more in detail with the products formed.

Nitronaphthalene was warmed with two parts of ordinary and one part of fuming sulphuric acid, and after 10 hours was poured into water. The α -acid separated out for the most part. From the mother-liquor the calcium salts of the α - and β -acids were obtained, and from the mother-liquor of these were obtained potassium salts, which gave two chlorides with PCl_5 , melting at 167° and 126° respectively.

The chloride melting at 167° is that of the δ -acid, obtained also by nitrating naphthalene- β -sulphonic acid; δ -nitronaphthalene sulphonic acid is thus an α -nitro- β -sulphonic acid. The chloride melting at 126° is that of β -nitronaphthalene sulphonic acid, which is identical with the third acid obtained by sulphonating α -nitronaphthalene. It is evident from this that the nitro group in β -nitronaphthalene sulphonic acid occupies the α -position. A number of salts of the δ acid are described.—T. L. B.

δ -Amidonaphthalene Sulphonic Acid. P. T. Clève. Ber. **21**, 3264—3267.

A DESCRIPTION of various salts and derivatives of the acid.

By suspending the amido-acid in absolute alcohol and treating with nitrogen trioxide, the diazo acid is obtained, $\text{C}_{10}\text{H}_6\text{N}_2\text{SO}_3$. By treatment in aqueous alcohol a violet azo-colour is obtained, which is changed into brown on the addition of alkalis. It is soluble in water.—T. L. B.

γ -Amidonaphthalene Sulphonic Acid. P. T. Clève. Ber. **21**, 3271—3276.

THE various salts and derivatives are described. Nitrogen trioxide acts very slowly on it, with formation of γ -diazonaphthalene sulphonic acid.—T. L. B.

Fluoresceïn. R. Meyer and O. Oppelt. Ber. **21**, 3376—3378

THE constitution of fluoresceïn is known, only the position of the oxygen atoms belonging to the resorcinol nuclei towards the methane carbon atom is not yet clear. If it be in para-position to one oxygen atom and in ortho to the other, its formula will be—

By the action of ammonia a body ought to be produced, which, in place of the oxygen residua of resorcinol would contain the ammonia residua—

If, then, the lactone ring could be broken, and a molecule of carbonic acid and water were given off a symmetric diamidophenylacridine would be formed, isomeric with chrysianiline and identical with benzothavine, which could be easily converted into phenylacridine. The authors have succeeded in preparing a body of the above formula by the action of ammonia on thiorescein. It is a yellow colouring matter which dyes wool a beautiful yellow. It forms a salt with caustic soda, crystallising in fine needles. By acidulating and precipitating with ammonia the original base is reformed. If, however, the alkaline solution be reduced with zinc dust a nearly colourless solution is obtained, which yields no precipitate on treatment with hydrochloric acid and ammonia.—A. L.

On Chromogenic Carbinols and the Constitution of Rosaniline Salts. V. v. Richter. Chem. Zeit. 12, 1641.

According to Richter, chromogenic carbinols are a class of compounds whose colour-producing properties depend on the replacement of hydrogen atoms, which are directly combined with carbon, by basic or negative radicals. Accordingly we have to distinguish between basic carbinols and carbinol acids. The latter are formed by the replacement of two or three hydrogen atoms in methane by a corresponding number of negative radicals, especially by nitrophenyl groups. With alkalis these give intense violet and blue salts, in which the carbinol hydrogen is replaced by alkali metals. The basic carbinols, on the other hand, contain amidophenyl groups and produce coloured salts with acid radicals. The rosaniline salts should be looked upon as belonging to this class.—F. W. T. K.

PATENT.

A Method for the Production of New Colouring Matters suitable for Dyeing and Printing. C. Dreyfus, Manchester. Eng. Pat. 9280, June 26, 1888. 6d.

PRIMULINE (this Journal 1888, 179) when diazotised and combined with an alkaline solution of β -naphthol, forms a red colouring matter. Hitherto this could not be applied directly for dyeing or printing purposes on account of its insolubility. The present invention consists in dissolving primuline in water, acidifying the solution, diazotising it with nitrous acid, and pouring the mixture into an alkaline solution of β -naphthol. The insoluble colouring matter is then filtered, washed, pressed, and dried, and rendered soluble by heating it (in a closed vessel or in one connected with an inverted condenser) with about $2\frac{1}{2}$ times its weight of sodium bisulphite of 50° Tw. to 100° C. The filtered solution is treated with salt, which precipitates the new product in the form of a yellow powder, which is very easily soluble in water and is decomposed by caustic alkali, with the formation of the above red colouring matter. If the soluble colouring matter be used for printing and afterwards developed on the fabric by steaming, a red colour is produced which is very fast to soap. In a similar manner maroons and oranges can be produced by substituting α -naphthol and resorcinol respectively, for the β -naphthol in the process described above.—T. A. L.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

PATENTS.

Improvements in Scouring or Dyeing Woollen Rugs or Skins with or without the Wool or Fur upon them, or any Woollen Fabric or Leather, and in Apparatus to be used for the Purpose. J. and J. C. Morland, Glastonbury. Eng. Pat. 329, January 7, 1888. 8d.

THIS apparatus for scouring skins, rugs, furs, or leather, consists of a revolving cylinder which has a number of brushes attached to its circumference and parallel with its axis, the cylinder being enclosed within a fixed casing. "The skin to be treated is laid on a table with the wool side uppermost, and whilst held by the workman is drawn forward, by the action of the brushes, over the surface of a roller which is parallel with the brush cylinder, and at such a distance from it that the brushes as they revolve act against and brush the wool. The roller may be prevented from turning by a pawl and ratchet wheel, so as not to allow the skin to be drawn in too rapidly, but can freely turn in the opposite direction when the skin is drawn back." Above the roller is a perforated pipe for the supply of the water, scouring-liquor, or dye-liquor, to the action of which the wool has to be subjected.—W. E. K.

Improvements in Machinery for Dyeing Yarns. J. B. McKay, Galashiels. Eng. Pat. 336, January 9, 1888. 8d.

THE bunks of yarn to be dyed are held in a distended condition upon vertical frames, each frame having a small reel at its upper end and a roller at its lower end. Each reel is fast on a horizontal shaft, and the sides of the vertical frame are hung loosely on the shaft, which rests on guide rails fixed along the sides of an oblong rectangular vessel, which constitutes the dye-vat. Suitable provision is made for a supply of steam for heating the dye-liquor contained in the vat. The series of shafts are moved gradually from one end of the vat to the other, and whilst being so moved are turned, so as to change the position of the bunks on the reels and rollers, by means of pinions which are fixed on the shafts and gear with a toothed rack fixed along one side of the vat. The shafts are moved along the vat by means of endless pitch chains at the sides, these chains having fixed to them studs which act on the shafts. The sprocket wheels which move the endless chains are by preference turned by means of ratchet wheels and driving pawls worked by eccentrics on a rotating shaft driven in any convenient way. When each shaft, with its vertical frame, has been moved from one end of the vat to the other, it is lifted up out of the vat by means of two other endless pitch chains at the sides, worked by means of continually rotating sprocket wheels. By these transferring pitch chains the frames are carried above the level of the vat and returned into the vat at the entering end, and this passage of the frames through the dye vessel may be repeated as often as necessary. There is also provision for lifting the whole of the frames simultaneously, to admit of any desired alteration being made in the dye-liquor.—W. E. K.

VII.—ACIDS, ALKALIS, AND SALTS.

On the Preparation of Phosphorescent Sulphides of Calcium and Strontium. E. Becquerel. Compt. Rend. 107, 892—894.

THE author has previously shown that by adding to a mixture of lime and sulphur before igniting, a small quantity of a certain substance, a much more brilliant phosphorescence is obtained. He has since discovered that the action of the latter compound is often only observed when that substance is impure or consists

of a variety of different bodies. Thus on calcining perfectly pure carbonate of lime with sulphur, the product is but slightly phosphorescent. If, however, previous to heating, traces of soda be added, the product becomes strongly luminous with a green light after the exposure. On the other hand, if traces of manganese or bismuth be added to the carbonate, after igniting with sulphur, the sulphide is hardly luminous, but becomes so if before calcining 0.5—1 per cent. of soda be added, showing a brilliant yellow or blue phosphorescence. Lithia acts like soda on carbonate of lime, causing the sulphide to emit a very intense green light after exposure. Potash, when quite pure, has no effect. On calcining oyster and other shells a phosphorescent fiery red mass is often obtained. The same effect was observed by the author when sodium carbonate containing traces of rubidium were added to the lime and sulphur before igniting.

The sulphide of strontium is, generally speaking, less luminous than that of lime. When prepared from the pure carbonate it shows a slight bluish-green phosphorescence; when traces of soda are present the colour is green.—A. R.

Action of Carbon Bisulphide on Clay—Production of Carbon Oxy-sulphide. A. Gautier. *Compt. Rend.* **107**, 911—913.

A PORCELAIN tube is filled with kaolin, previously calcined at a red heat, and placed in a combustion furnace heated to a white heat, the air replaced by CO_2 , and a current of dry CS_2 then passed over the kaolin. The gas which leaves the tube consists of 60—64 per cent. of carbon oxy-sulphide, 35—39 per cent. of CO , traces of H_2S and CO_2 , and the remainder of "sulphocarbonic acid" (probably meant for carbon bisulphide). The higher the temperature the more COS is formed. The gases traverse a flask cooled with ice water, where most of the CS_2 is deposited; they are then washed in caustic potash, which removes H_2S and CO_2 , whence they pass through a column of acid cuprous chloride to absorb the CO . Any remaining traces of CS_2 are then removed effectually by alcoholic aniline, and the gas is finally passed over pumice stone saturated with sulphuric acid. It is then perfectly pure COS . The residue in the tube is found, on carefully breaking the latter, to contain at the extreme end brilliant white crystals of sulphide of silicon. In place of the kaolin there is a substance of a leaden appearance in which numerous very hard crystals are embedded. The latter emit H_2S in moist air. Water acts on them with difficulty and gives gelatinous silica and alumina. It appears likely that sulphur has taken the place of O, and a kind of polysulphate of alumina has been formed. When carbon bisulphide is passed over ignited alumina very little COS is formed. The gas is, however, obtained almost pure by passing the vapour of sulphur over a mixture of alumina and charcoal at a white heat.

—A. R.

Salt Beds in New South Wales. "Sydney Daily Telegraph," November 28, 1888.

WHAT may be a discovery of great value has been made at Ellalong, near Maitland, and about 16 miles from Allandale station. There a deposit of crystallised salt, 4 ft. thick in places, has been found, and it is expected that a body of rock salt will be reached below. Mr. Hilton, an expert, expresses the opinion that a similar deposit will be discovered at Ellalong. Something like 100,000 tons of salt per annum are used there, and the price is 5l. 10s. per ton. Thus, such a discovery would be of great value. A syndicate has secured 400 acres of the land, and the value of the latter will be thoroughly tested.—W. S.

Improvements in the Method of and Apparatus for Manufacturing Hydrated Phosphates and in Recovering By-products therefrom. L. G. G. Daudenart, Brussels, Belgium. Eng. Pat. 17,181, December 14, 1887. 11d

THE phosphate to be treated is in all cases first washed with water to dissolve out all soluble matter, and to remove

the lighter earthy impurities. It is then treated with hydrochloric acid from a subsequent operation forming a solution of calcium chloride and acid phosphates of lime. To this is added magnesium hydrate, whereby the bicalcium hydrated phosphate is precipitated and calcium and magnesium chlorides remain in solution. Magnesium carbonate is added and carbonic acid gas passed in under a pressure of two to three atmospheres, the whole of the lime being rapidly thrown down as carbonate, the solution now containing only magnesium chloride. The inventor states that the conversion is much more rapidly effected in this manner than if magnesia be merely suspended in the liquid and carbonic acid gas passed in. The chloride of magnesium solution is evaporated until it has the composition $\text{MgCl}_2 + 17 \text{H}_2\text{O}$, this is thrown in regulated quantities and at regular intervals upon the red-hot sole of a special basin-shaped orin of furnace. Hydrochloric acid is at once given off, associated with 16 molecules of water, and this is again used in the first process. The anhydrous magnesia remaining can either be re-hydrated by boiling with water at a pressure of two or three atmospheres, or, if overheated, dissolved in hydrochloric acid and the chloride worked up again. Hydrated magnesia may also be obtained from seawater by treating with lime, and hence the manufacture of hydrated bicalcium phosphate may be united with the extraction of magnesia from this source.—S. G. R.

Improvements in the Treatment of Alkali Waste to obtain Sulphuretted Hydrogen and other Products, and in Apparatus Employed to obtain these Substances. Jas. Hargreaves, T. Robinson, and Jno. Hargreaves, Widnes. Eng. Pat. 1371, January 30, 1888. 6d.

I. ALKALI waste is mixed with sufficient clay "to combine and form cement with the lime contained in the waste." The mixture is formed into bricks, which are placed in a series of chambers, superheated steam being passed through the mass, in order to drive off the sulphur as sulphuretted hydrogen. The heating of the mass is then continued to form cement.

II. Oxidised alkali waste is mixed with both coal and clay before heating, in order to reduce the sulphur-oxygen compounds to sulphides.

III. If it be intended to treat alkali waste with carbonic acid in order to obtain sulphuretted hydrogen, a chamber is employed, with a series of shelves placed one above another, and upon which shelves, by mechanical means, the waste is constantly moved, so as to expose fresh surfaces to the carbonic acid. The waste is allowed to fall from one shelf to another below, whereas the carbonic acid passes through the chamber in an opposite direction. After carbonation the waste is exposed to the air, in order to oxidise any undecomposed sulphides to sulphate. The latter is removed by washing, and the residue intimately mixed with clay. The mixture is heated with highly superheated steam, whereby carbonic acid is liberated, which is caused to act on fresh alkali waste, while cement is produced at the same time.—S. II.

Improvements in Treating Sulphides of Sodium and Potassium to obtain Sulphuretted Hydrogen, and in Apparatus Employed therein. A. M. and J. F. Chance, Oldbury. Eng. Pat. 1495, February 1, 1888. 8d.

POTASSIUM of sodium sulphide is dissolved or mixed with water and introduced into a series of vessels connected by pipes, and furnished with inlet and outlet ways. Gases rich in carbonic acid, preferably gases from a closed lime-kiln, are then pumped into the first vessel of the series. The carbonic acid at once decomposes the sulphide, sulphuretted hydrogen being evolved, which is driven forward into the second vessel, where it meets with further quantities of sulphide, whereby it is dissolved with the production of sulphhydrate. The gases finally issuing from the last vessel contain no sulphuretted hydrogen, and are allowed to escape into the air. Gradually nearly all the sulphide is decomposed in the first vessel, when the carbonic acid acts on the sulphhydrate in the second vessel, the evolved gases rich in sulphuretted hydrogen being

conducted to a gasholder. As soon as the evolution of sulphuretted hydrogen diminishes, the gases are again passed through a vessel filled with sulphide for the purpose of forming sulphhydrate and so forth. The apparatus employed is described in Eng. Pat. 8666, of 1887 (this Journal 1888, 210).—S. H.

Improvements in Making Sulphide of Zinc. J. Wilson, Leith. Eng. Pat. 1516, February 2, 1888. 4d.

A SOLUTION of sodium sulphide free from carbonic acid is used for precipitating zinc salts to produce zinc sulphide. The sulphide of soda made by calcining sulphate of soda with coal, may be freed from carbonic acid by treatment with sulphate, chloride or sulphide of lime or magnesia, or with sulphide or chloride of barium or strontium. The sulphide of soda may also be obtained free from carbonic acid by mixing the sulphate of soda with sulphate of lime, barium, or strontium before calcining it with coal, or the sulphide of soda may be made by treating sulphate of soda with sulphide of lime, barium, or strontium.—E. E. B.

Improvements in the Manufacture of Chlorine. H. W. Deacon and F. Hurter, Widnes. Eng. Pat. 2104, February 11, 1888. 6d.

THIS invention relates to the Deacon process, wherein chlorine is produced from hydrochloric acid gas by means of oxygen and a catalytic substance. It has been found that it is of great advantage to introduce the hydrochloric acid gas into the decomposer in as dry a condition as possible. In order to secure the dry condition of the gas, the mixture of hydrochloric acid and steam, as given off during the process of manufacturing salt-cake, is first cooled and afterwards made to ascend a tower, where it meets with a descending stream of strong sulphuric acid.—S. H.

Improvements connected with the Manufacture of Chlorine. H. W. Deacon and F. Hurter, Widnes. Eng. Pat. 2311, February 15, 1888. 6d.

THE gases passing out of a decomposer used in the Deacon chlorine process always contain some hydrochloric acid, which has passed undecomposed through the apparatus. It was customary to remove the hydrochloric acid by washing with water, but the aqueous acid thus produced was so dilute as to be valueless. It is now proposed to remove the hydrochloric acid by bringing the gases into intimate contact with "Weldon mud." The latter readily absorbs the hydrochloric acid gas, thereby evolving chlorine. In order to carry out this intention, Weldon mud is run down a tower, filled with flint, whereas the gases from the decomposer pass upwards through the tower. The amount of Weldon mud run down is so regulated as to leave a little manganese dioxide undissolved. The resulting black liquid is ultimately worked off in an ordinary Weldon still.—S. H.

Improvements in the Manufacture of Sulphuric Anhydride, and Apparatus to be Employed therein. E. B. Ellice-Clark, London. Eng. Pat. 3116, March 1, 1888. 8d.

Pure, dried oxygen gas is pumped through a pyrites, brimstone, or other sulphur burner in sufficient quantity to burn all the sulphur into sulphurous anhydride, and further to convert this into sulphuric anhydride. The burner is closed to prevent any admission of air, and is provided with concentrating pans for the utilisation of the waste heat. The mixture of sulphurous anhydride and oxygen is passed through a chamber in which any dust is deposited, and then through a series of tubes filled with material which exerts a catalytic action, preferably platinised asbestos, the temperature being carefully regulated. The sulphuric anhydride formed, mixed with traces of sulphurous anhydride and oxygen, is condensed, and the last traces of sulphuric anhydride then removed by passage through concentrated sulphuric acid. The residual sulphurous anhydride and oxygen, if any, pass back again through the pump. A drawing of the apparatus is given.—S. G. R.

Improvements in Treating the Liquors known as Yellow Liquors draining from Alkali Waste Heaps to obtain Sulphuretted Hydrogen, and in Apparatus Employed therein. A. M. and J. F. Chance, Oldbury. Eng. Pat. 3182, March 2, 1888. 6d.

THE yellow liquors which contain calcium sulphhydrate, together with polysulphides, are placed in closed vessels and treated with gases containing carbonic acid in the manner described in Eng. Pat. 8666 of 1887 (this Journal, 1888, 210). The yellow liquors may be also worked up along with alkali waste, by mixing the latter with yellow liquors instead of with water, and carbonating the two together.—S. H.

Improvements in the Manufacture of Sulphide of Sodium or of Sulphide of Potassium from their respective Sulphates. F. H. Gossage and T. T. Mathieson, Widnes. Eng. Pat. 3218, March 2, 1888. 4d.

THE object of this invention is to manufacture alkaline sulphides from their sulphates without destroying the lining of the furnace in which the reduction is performed. For this purpose the inventors add to the mixture of sulphate of soda, or sulphate of potash, and coal, a sufficient quantity of sodium chloride, the presence of which prevents the injurious action of the sulphide on the lining. Eight parts of common salt to 20 parts of the sulphate are generally found sufficient. The mixture of sulphide and salt formed by the fusion in the furnace may be drawn into open vessels and cooled before lixiviation without danger of oxidation. The mass is then lixiviated and the solution worked up for various purposes.—S. H.

Improvements in the Manufacture or Production of Sodium-Meta-Sulphite. A. Boake, F. G. A. Roberts, A. Shearer, and W. B. Giles, Stratford. Eng. Pat. 4262, March 20, 1888. 8d.

SULPHUR dioxide gas is passed through a solution of sodium carbonate, bicarbonate, or hydrate. The solution is kept at from 110° F. to the boiling point of the liquid, preferably gently boiling. When the gravity of the liquid is about 1.450, and no more sulphur dioxide is absorbed, the solution is run off, cooled, and allowed to crystallise.—S. G. R.

Obtaining Sulphur, &c. F. B. Rawes, Stratford. Eng. Pat. 1393, March 22, 1882. (Second Edition.) Amended November 2, 1888. 11d.

THE emendations consist in the deletion of part of the second claim, and the whole of the third and sixth claims, relating to apparatus for purifying carbon dioxide; for treating hydrogen sulphide with iron oxide to obtain free sulphur; and also to the use of by-products obtained by such processes. (See this Journal 1882, 454.)—O. H.

Apparatus or Appliances in combination with Furnaces for Roasting Pyrites and other Minerals containing Sulphur, for Cooling the Sulphurous Gases given off therefrom. H. Albert, C. Fellner, and C. Ziegler, Bockenheim, Germany. Eng. Pat. 15,980, November 5, 1888. 8d.

THE very hot gases issuing from the burners, which are often injurious to both Glover tower and chamber, are passed on their way to the Glover tower through a brick chamber subdivided by a partition and furnished with ranges of pipes. The pipes are  shaped, and the gases pass over them in a descending and ascending direction, and in the reverse way to that in which the air or other cooling medium travels within them. The heat thus taken up may be utilised for heating, drying, evaporating, or other purposes. The specification is furnished with plans.—S. G. R.

PATENTS.

Improvements in and connected with the Manufacture of Cement, and Apparatus for Use therein. W. Joy, Northfleet. Eng. Pat. 1978, February 9, 1888. 11d.

THE patentee charges cement kilns partly with a mixture of slurry and fuel, and partly with slurry unmixd with fuel. The constituents may be used either wet or dry. The kiln is started and then feeding continued according to Eng. Pat. 9154 of 1885, or 15,751 of 1885 (this Journal, 1886, 327), until the lower portion of the charge is converted into a "clinker." After this, feeding is continued alternately with a mixture of slurry and fuel, and with neat slurry, wherever a glow appears on the surface. The relative quantities of mixture to neat slurry are decreased as the kiln fills up. When a kiln has been sufficiently charged it is allowed to burn out.

In preparing the slurry the chalk is crushed by passing through rolls and then run into the pan of an edge-runner mill. The clay to be mixed with the chalk is placed, with or without water, in the pan, and the mixture passes through the perforated or grated bottom into a chamber below, where it is further mixed by means of stirrers. From this chamber it passes into a horizontal cylinder, where it is still further mixed and along which it is propelled by means of screw-like arms. It may then be delivered on to rolls or mill-stones, or taken direct to the drying floors.

In the drying of the slurry the products of combustion from the kilns are utilised.—T. L. B.

Improvements in and relating to the Manufacture of Lime and of Natural and Artificial Cements. M. H. Heys, Swancombe. Eng. Pat. 1980, February 9, 1888. 6d.

ALTERNATE layers of fuel and raw material are packed in the kiln and the charge burnt from the top. As soon as the fuel is burnt through to the bottom the eye of the kiln is closed to prevent access of air. After cooling the mass is slaked; the portions remaining unslaked may then be ground and used as plaster, and the fine portions may be mixed as a slurry with siliceous material and recalcined.

—T. L. B.

Improvements in the Manufacture of Artificial Stone. J. Brunton and L. Griffiths, London. Eng. Pat. 2803, February 24, 1888. 6d.

CRUSHED granite, slag, or limestone is mixed with an alkaline silicate, an alkaline carbonate, an acid (such as azotic, sulphuric, acetic) and hydraulic lime or Portland cement. The compound can be formed in moulds. When hard, the blocks may be immersed in a bath of silicate of soda or potash for about 48 hours to still further harden them, after which they are dried. Colouring matters may be introduced. Metal bars or the like may be imbedded in the material to give strength.—T. L. B.

Cyanide of Potassium as a Lixivation Agent for Silver Ores and Minerals. L. Janin. The Eng. and Min. Journ. 46, 548—549.

THIS paper consists of a description of a series of experiments undertaken, in consequence of contradictory state-

ments, to ascertain the solubility of silver and some of its compounds in solutions of potassium cyanide. Sulphide of silver dissolved to the extent of 30 per cent. when submitted to an excess of a 1 per cent. solution for 12 hours at a temperature of about 35° C. Under similar conditions the solubility rapidly increased as the solution was made more concentrated, until 10 per cent. was reached, when 98.5 per cent. of the sulphide was dissolved. With a 20 and a 25 per cent. solution the amount dissolved was 99.8 per cent. In the presence of oxide and other compounds of copper the solubility was reduced. Cement silver was next tried, and it was found that as the strength of the solution increased the solubility decreased, 24.7 per cent. dissolving in 500 cc. of a $\frac{1}{2}$ per cent. solution after 12 hours, whilst only 17.6 per cent. dissolved in the same time in a similar quantity of a 25 per cent. solution. The explanation suggested is that more hydrogen is liberated in the stronger solutions and causes stronger polarisation. Samples of various silver ores were then experimented upon with a 5 per cent. solution, and the results are given side by side with the results obtained by Russell's process. In 19 out of the 22 cases cited, an advantage is shown over the latter method, in some cases two or three times the amount of silver being extracted. As a rule the advantage is greatest when the ores are base. When the ore is roasted and chloridised the cyanide solution possesses a slight advantage over hyposulphite. Cyanide dissolves considerable quantities of gold from raw and roasted auriferous pyrites, and experiments on a few tailings showed a superiority of the cyanide method over Russell's process in this respect.

The author recommends the use of cyanide for silver extraction, and the electrolytic method for obtaining the silver from solution, potassium sulphide and flowers of sulphur being impracticable. The following objections to the process are pointed out:—1. The poisonous quality of the solution. 2. The solution when strong is easily decomposed by exposure to heat and air. 3. The excessive cost of the chemical. 4. Its great solvent powers for base metals. This last objection is the only valid one, and is more emphatic with roasted than with raw ores. But even this can be overcome by first washing the roasted ore with water, leaching with hyposulphite, and using the cyanide only to extract a further quantity of silver.—A. W.

The Oxidation and Cleansing of Tin. L. Vignon. Compt. Rend. 108, 96—98.

CRYSTALLINE tin, which has been deposited upon zinc from neutral solutions of stannous or stannic chlorides, contains, after a few days' exposure to the air, a fourth or third of its weight of stannous oxide; its surface being coated with oxide it does not fuse when heated, but burns like tinder. The same properties are to be observed in powdered tin, made by shaking molten tin in a wooden box.

This throws light upon the necessity for the use of zinc chloride, ammonium chloride, resin, &c. in tinning and soldering. For if the infusible tin be heated with solid zinc chloride a bright button and a brown dross are obtained; the latter is soluble in water with formation of a white precipitate, which dissolves in hydrochloric acid, giving stannous chloride. Again, if infusible tin be heated with ammonium chloride, ammonia is evolved and stannous chloride formed:

It is evident, then, that the use of these fluxes is to dissolve the oxide of tin and obtain a bright surface. This shows that tin is notably oxidised in both dry and moist air at the ordinary temperature. (Compare this Journal 1889, 62.)—A. G. B.

Alloys. W. Chandler Roberts-Austen. J. Soc. Arts, 36, 1111—1118; 1125—1133; 1137—1146. Three Cantor Lectures.

THE lectures commence with a sketch of the early investigations on alloys, and the development of views in

respect to their constitution from the time of Réaumur in 1722 to that of Matthiessen in 1860. Réaumur, who studied the molecular change produced in a metal by heat, explained the hardening of steel by stating that when hot steel is rapidly cooled the "sulphur and salts" cannot return to the molecules, but remain in the interstitial spaces, which comes very near to the modern view that a metal may, under certain conditions, pass from one allotropic state to another. Muschenbrock examined the cohesion of alloys and made experiments on their tensile strength, and pointed out in the early part of the 18th century the importance of working on the tenacity of metals. Duhamel appears to have been the first to show the necessity of using, for experiment, pure materials, and Regnault showed that the specific heat of certain fusible alloys was greater, near 100, than the mean specific heat of their constituents. Matthiessen's very important work on the electrical resistance of metals and alloys led him to the conclusion that metals exist in many cases in allotropic forms.

Alloys can be produced in three ways:—(1) by fusion; (2) by compression of the powders of the constituent metals; (3) by electro-deposition. The following metals evolve heat when united by fusion:—aluminium and copper, platinum and tin, arsenic and antimony, bismuth and lead, gold and just-melted tin; while lead and tin in uniting absorb heat. Equivalent proportions of the powders of tin, lead, and bismuth mixed with eight equivalents of mercury, produce a reduction in temperature from $+17^{\circ}\text{C.}$ to -10°C. Sprig's work on the production of alloys by compression was next described. He produced by the compression of the powders of certain metals solid blocks of the same, having the same physical properties as the metals produced by fusion; thus bismuth became crystalline, &c., and he was led to the conviction that alloys could be produced in the same manner. The powders of bismuth, lead, tin, and cadmium in the proper proportions were compressed, and an alloy produced which melted below 100°C. Instances of the electro-deposition of alloys were given, such as the deposition of brass from a solution of copper and zinc sulphates, and the production of red, rose-coloured, and green gold by using suitable mixtures of gold, silver, and copper.

The separation of the constituent metals of alloys by electrolysis has so far not been effected. After referring to Obach's attempts to decompose sodium amalgam, the author describes his own experiments with alloys of lead and gold, and lead and silver. By melting the alloy in two cavities in a fire brick communicating one with the other at the base by a narrow channel, and passing a strong current of electricity through it, it was found that no separation of the metals took place even while the current was passing through the alloy.

The second lecture is devoted very largely to the influence of traces of impurities on metals. 0.05 per cent. of tellurium converts bismuth into a minutely crystalline mass. 0.2 per cent. of bismuth renders gold useless for coinage. 0.01 per cent. of antimony in copper spoils it for the manufacture of brass—a small quantity of tin or other impurities reduces the conductivity of copper enormously, and so important is this commercially, that as Preece points out, a cable made of the copper of to-day will carry twice the number of messages that a similar cable of less pure copper would in 1858, when the influence of impurities in this respect was not understood. Prof. Roberts-Austen then describes his own recently-published research* on the effect of traces of impurities on the tensile strength of gold, and which is of extreme importance, inasmuch as it establishes a law in connexion with the effect of these impurities. Gold was chosen for the following reasons:—it is possible to purify it to a high degree; it is not liable to oxidation; and the accuracy of the results is not affected by the presence of occluded gases. Pure gold has a tensile strength of 7 tons per square inch with 25 per cent. elongation, and its atomic volume is 10.2. Small quantities of impurity about 0.2 per cent. were added, and the metal tested with the following results:—

Name of added Element.	Tensile Strength. Tons per Sq. In.	Elongation per Cent. (on 3 Ins.).	Impurity per Cent.	Atomic Volume of Impurity.
Potassium ..	0.5 (less than)	Not perceptible	0.2 (less than)	15.1
Bismuth....	0.5 (about)	"	0.210	20.9
Tellurium...	3.88	"	0.186	20.5
Lead.....	4.17	4.9	0.240	18.0
Thallium...	6.21	8.6	0.193	17.2
Tin.....	6.21	12.3	0.196	16.2
Antimony...	6.0 (about)	Qy.	0.203	17.9
Cadmium...	6.88	44.0	0.202	12.9
Silver.....	7.10	33.3	0.200	10.1
Palladium ..	7.10	32.6	0.205	9.4
Zinc.....	7.54	28.1	0.205	9.1
Rhodium...	7.76	25.0	0.210 (about)	8.4
Manganese .	7.99	20.7	0.207	6.8
Indium.....	7.99	26.5	0.200	15.3
Copper.....	8.22	13.5	0.193	7.0
Lithium....	8.87	21.0	0.201	11.8
Aluminium .	8.87	25.5	0.186	10.6

These results prove that metals having a high atomic volume, when present in small quantity, diminish the tenacity and extensibility of gold, while those with an atomic volume the same as gold, or less, either increase or do not affect these properties. This law is supported by outside evidence in the case of other metals: thus, iron with an atomic volume 7.0 is rendered more tenacious by small quantities of carbon with a low atomic volume, and is prejudicially affected by sulphur, arsenic, and phosphorus, with atomic volumes 15.4, 13.3, and 14.8 respectively. The effect of manganese on iron is not yet proved, but from its having the same atomic volume it may be surmised that it does not act prejudicially.

The third lecture relates chiefly to the colours of metals and some of the various means employed to utilise them artistically, such, for instance, as the production of a patina on metals and alloys by pickling. Analyses of some of the alloys and the compositions of some of the pickling solutions used by the Japanese, who are proficient in this art, are given. The latter all contain verdigris and sulphate of copper, and there may also be present vinegar, nitre, salt, and sulphur. The colour of the patina is regulated by the solution used as well as by the impurities in the metal or the composition of the alloy. There is another Japanese metallurgical art which the author is desirous of seeing established in this country, viz., "mekumé" or "wood-grain."

It is made by soldering together thin sheets of various metals layer upon layer, drilling conical holes into them, and hammering flat or punching prominences and filing those down to the surface of the metal, thus producing complicated sections of the banded alloys, and developing the colours by pickling.—A. W.

PATENTS.

Improvements in the Manufacture of Sodium and Potassium. P. M. Justice, London. From H. Y. Castner, New York, U.S.A. Eng. Pat. 7395, June 2, 1886. (Second Edition.) 6d.

See this Journal, 1886, 538, and 1887, 174—176.

Improvements in Apparatus for Producing Aluminium and other Metals and their Alloys and Operating the same. W. L. Wise, London. From "The Schweizerische Metallurgische Gesellschaft," Laufen, Switzerland. Eng. Pat. 16,853, December 7, 1887. *Sd.*

The apparatus consists of an iron box or framework in which blocks of carbon united by a cement, such as coal-tar, are packed so as to form a kind of crucible, with a small channel from its base through the iron case to the exterior. This crucible is connected by suitable means with the negative pole of a dynamo. Inside the crucible are suspended a series of carbon blocks, and these are connected to the positive pole. Granulated copper is introduced into the crucible and the current passed, whereby the copper is melted and becomes the negative electrode. Clay or alumina is now added, the positive electrode being raised just out of contact with the copper. Aluminium bronze is produced and can be tapped through the bottom, fresh material being added at the top. Aluminium can be produced by using alumina alone, and silicon will enter into the aluminium bronze if a silicious clay be used. Drawings of the apparatus are given.—A. W.

Improvements in the Manufacture of Sodium, Potassium, and Metals of the Alkaline Earths, and in Apparatus therefor. H. H. Lake, London. From C. Netto, Dresden, Germany. Eng. Pat. 17,412, December 17, 1887. *Sd.*

This is a continuous method for making sodium from caustic and carbon at low temperatures. The apparatus consists of a vertical iron retort placed in a convenient furnace, with a condenser at the top, and with a hydraulic trap or other suitable arrangement at its base. It is filled to about one-half with incandescent charcoal, and fused caustic soda is continuously fed in at the top, falling on to and trickling through the charcoal. Sodium distils over and the carbonate of sodium produced runs down to the bottom of the retort, and can be syphoned off continuously or intermittently, and thus prevented from interfering with the continuous action of the process. By this means sodium can be produced at a much lower temperature and more regularly than when the carbonate of sodium is not removed. A vertical section of the plant is given, together with various means for drawing off the fused carbonate without admission of air to the apparatus.—A. W.

An Improved Process for the Manufacture of Sodium. H. S. Blackmore, Mount Vernon, U.S.A. Eng. Pat. 15,156, October 22, 1888. *6d.*

The following mixture is heated in an iron cylinder to dull redness for 20 minutes, and afterwards to a white heat:—27.5 parts of calcium hydrate, 31.1 parts of ferric oxide, 30.9 parts of dry sodium carbonate, and 10.5 parts of charcoal, or other carbonaceous matter. Caustic soda is first produced, and the organic matter reduces the ferric oxide to metallic iron, which in turn reduces the soda; the metallic sodium distils off and is suitably condensed. The residue consists of ferric oxide and quick lime, and it is only necessary to slake the latter when the mixture can be used repeatedly for treating fresh quantities of sodium carbonate and charcoal.—A. W.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

PATENTS.

Improvements in the Utilisation of Waste Products from Electrical Batteries. O. C. D. Ross, London. Eng. Pat. 208, January 5, 1888. *6d.*

The waste solutions from electrical batteries still contain a considerable proportion of sodium or potassium nitrate and

free nitric or nitrous acid partly or wholly dissolved or decomposed. These partially exhausted acid solutions are mixed with about an equal weight of bones or coprolites, and the mixture allowed to stand for two to four weeks, whereby the phosphate present is converted into the superphosphate. The undissolved solid portion is afterwards boiled in the resulting phosphate solution and the whole evaporated to a partially solid magma. To the mixture is then added some dry substance useful as a manure, such as bone-meal, powdered coprolites, straw, bran, potassium, or calcium sulphate. The application of the waste products of electric batteries in the stead of sulphuric or hydrochloric acids is the peculiar object of the patent.—V. H. V.

Improvements in Voltaic Batteries. E. Tyer, London. Eng. Pat. 3312, March 3, 1888. *Sd.*

This invention relates to a electric cell so arranged that the extent of the contact of the zinc pole with the exciting liquid can be readily varied or entirely prevented without exposure of the pole to atmospheric action, and with constant maintenance of the amalgam on the surface. This is effected by placing at the bottom of the cell an annular trough charged with mercury, into which is immersed a vertical hollow cylinder of zinc. Over this is placed a bell of glass or ceramic ware made with a stem projecting upwards through a guide hole provided with a setting screw, so that the bell may be fixed at any desired height. At the lowest position of the bell the exciting liquid is prevented from coming in contact with the zinc; but by raising the bell more or less a greater or less surface of the zinc is exposed to the exciting liquid. From the mercury trough an insulated wire is led to a terminal screw. A boss arrangement may be fixed in the centre of the element to occupy part of the space within the bell, so that on alteration of the position of the bell there is less displacement of the level of the liquid within the bell.—V. H. V.

Improvement in the Manufacture of Electrical Dry Elements. C. Gassner, junior, Mayence, Germany. Eng. Pat. 10,415, July 18, 1888. *4d.*

The object of this patent is to facilitate the formation of a layer of hydrated oxide of iron on the carbon electrode described in Eng. Pat. 16,810 of 1886 (this Journal, 1887, 674). This is effected by bringing carbon saturated with ferric chloride in some liquid which shall react with the chlorine, thereby precipitating hydrated peroxide of iron. Of the various mixtures and solutions proposed are the alkaline hydroxides, ammonium chloride, zinc chloride, or oxide; or glue, gelatine and other such substances in the presence of an ammonium salt, so that the ammonia liberated by the current combines with the chlorine. The depolarisation by the freshly-precipitated hydrated oxide is effective and permanent.—V. H. V.

Improvements in Galvanic Batteries. D. Humphreys, New York, U.S.A. Eng. Pat. 14,522, October 9, 1888. *Sd.*

The object of the invention is the distribution of a current of air over the negative pole of galvanic cells, and the agitation of the liquid partly by a mechanical device and partly by the air current. By means of a crank-shaft, perforated cross tubes or rods are alternately dipped into and removed from the acid liquid, while by the same crank-shaft a current of air is forced from a pair of bellows through the perforations. The poles are also removable from the acid liquid by a vertical rod, working on a cross-piece provided with a cam wheel. A bichromate cell to which this mechanism is attached shows a high electromotive force and a low resistance. The aerating process agitates the liquid, thus causing a uniform reduction of the bichromate, while at the same time the air not only removes sedimentary matters, but also dislodges and in part combines with the liberated hydrogen. The mechanism which produces the vertical motion of the cross-rods, and forces the air through the liquid is described fully in the specification.—V. H. V.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

The Testing of Lards. Meeting of Society of Chemists in Hamburg. Chem. Zeit. 12, 1660.

LANGFURTH has been carrying out experiments for the purpose of discovering a method of distinguishing between ordinary and artificial lard. The latter is imported from America, and similar products are manufactured in Europe. All artificial lards prepared from vegetable oils (purified cotton-seed, especially earth-nut oil) and stearin (chiefly suet pressings obtained in the manufacture of artificial butter) are coarsely crystalline on solidifying, and show a more or less polished surface, whereas true lard, whether crude or refined, exhibits a finely-crystalline structure and a dull wrinkled surface. When cotton oil is present, artificial lards slowly turn brown on the addition of concentrated nitric acid of 1.4 sp. gr.; they give an immediate blood-red colour on treatment with concentrated sulphuric acid, carbon dioxide being evolved at the same time. In the elaidin test, brown drops are formed in the crumbly mass. Artificial lards all show a high melting point ($46-48^{\circ}\text{C}$), as well as a very high iodine value ($60-64$), and a very high specific gravity ($0.862-0.864$, at 100°C). The quantity of oleic acid calculated, according to Darcian, from the solidification point, is always lower than that obtained by the iodine method, whereas with pure fats we get the reverse, or, more usually, agreement of the values. The European artificial lards usually contain a small quantity of borax and too high a percentage of water. Since the investigation of lards which solidify at 40° is difficult, especially when the colour tests have to be applied, Langfurth proceeds in the following manner:—1 kilo. of the lard under examination is wrapped up in strong linen, and slowly pressed and filtered at the ordinary temperature; a limpid yellow oil is obtained. With artificial lards this represents 30–40 per cent., and contains most of the vegetable oils. In this case it has a higher specific gravity ($0.916-0.918$, at 18°C) than the oil obtained from pure lard ($0.912-0.914$ at 18°C). The iodine value bears a fixed relation to the specific gravity. The oil should always be carefully filtered and dried before the above colour reactions are tried, and comparative tests with oil from true lard should be carried out. Free fatty acids, too, must be absent. The usual analytical tests serve for the detection of other vegetable oils, such as palm oil, cocoa-nut oil, and sesame oil.—F. W. T. K.

Vegetable Fats. H. Jacobson. Zeits. f. physiol. Chem. 1888, 32.

THE crude fats investigated were prepared from the seeds of beans, peas, vetches, and lupines respectively, in the chemical factory of H. Trommsdorff, in Erfurt. The powdered seeds were first extracted with strong alcohol. The residue obtained after expelling alcohol was next treated with ether. After saponifying the fats with strong soda lye the dry soap was treated with ether, petroleum spirit, or chloroform, and it was found that these removed a considerable quantity of some unknown substance. After extraction with ether the residual soap was decomposed by boiling with dilute hydrochloric acid. The free fatty acids formed green masses which were fairly soft at the ordinary temperature. On digesting these with a little water and a large excess of lead oxide, a hard mass was obtained. This mass was ground up and then treated for several days with ether, in order to dissolve the greater portion of the lead salts. The residue was boiled with hydrochloric acid in order to obtain the solid fatty acids.

In this way the crude fats were split up into four parts:—(1.) Mother-liquor of the soap lye. (2.) Ether extract of the sodium soap. (3.) Ether extract of the lead soap. (4.) Solid fatty acid.

The fat from beans contained only a small quantity of volatile fatty acid, probably valerianic acid. According to the quantity of phosphorus found, the fat contains

19.27 per cent. of lecithin. Probably a portion of the phosphorus originates from some other source than lecithin. From the ether extract of the sodium soap a substance was obtained which closely resembled animal and vegetable cholesterins. The crude fat contains 76 per cent. of oleic acid and 13.5 per cent. of solid fatty acids, the latter chiefly consisting of palmitic acid.

The fat obtained from vetches contains only a small quantity of volatile fatty acids. Lecithin and cholesterol were shown to be present. A portion of the fatty acids is probably present in the form of compound ethers of cholesterol.

The fat from peas contains rather more volatile fatty acids than the two preceding fats. It also contains lecithin, cholesterol, and another body which is probably ceryl alcohol. Stearic acid is not present, or at the most as a trace. The solid fatty acids consist mainly of palmitic acid and contain traces of a fatty acid which melts at $74-75^{\circ}$.

The fat from lupines contains only a small quantity of volatile fatty acids. Lecithin and a considerable quantity of cholesterol were found, and an alcohol obtained which was probably ceryl alcohol. The solid fatty acids chiefly consist of palmitic acid and a small quantity of what is probably arachidic acid.—F. W. T. K.

PATENTS.

Improvements in Machines or Apparatus for Testing Lubricants. A. J. Van Alstein, Antwerp, Belgium. Eng. Pat. 1986, February 9, 1888. 8d.

IN this patent a machine is described which is arranged to indicate automatically on a scale the lubricating power of any sample of oil. A testing roller rotates under the bearing of one end of a compound lever, along the furthest arm of which a weighted runner is moved by a screw motion. When the pressure is so strong as to prevent the oil from any longer exercising its lubricating action, the machinery is automatically thrown out of gear, and the position of the weighted runner on the arm of the lever indicates on the scale the lubricating power of the oil. Drawings of the machine are given.—W. L. C.

An Improved Mucarial Antiseptic Soap. J. Thomson, London. Eng. Pat. 6939, March 9, 1888. 6d.

CARBOATE of mercury, prepared by heating yellow oxide of mercury with carbolic acid at a temperature of 212°F ., and then adding caustic potash or soda in excess, or a biacyanide of mercury, is mixed with soap in suitable proportions. The proportions the patentee considers advisable are such that the finished soap may contain, of mercury, for toilet soap, $\frac{1}{10}$ to 1 per cent., for antiseptic soap, 1 to 3 per cent.

—C. C. H.

An Improved Soap powder, and the Method or Means of Manufacturing the Same. J. M. McCallum, Eng. Pat. 9796, July 5, 1888. 4d.

PARAFFIN oil (usually about 9 per cent. on the total other ingredients) is incorporated with soap, with alkali recovered from the manufacture of caustic lye, and with other salts. The mass is then dried and ground to a fine powder.

—W. L. C.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

Oxalate of Manganese. J. Castelaz. Bull. Soc. Chim. 50, 645–647.

THIS salt, which is used extensively for mixing with drying oils, is best prepared by neutralising the perfectly pure carbonate, free from lime and iron, with a solution of oxalic acid. When the oxalate is heated with oil to

150° C. the same decomposition takes place as when it is heated alone, viz., carbon monoxide and dioxide are given off and manganese monoxide remains behind.

Discussing the advantage oxalate of manganese has over other drying agents for oil, the author remarks: Lead oxides or the acetate give a varnish which is both liable to crack and tarnish.

Manganese dioxide is practically insoluble in oil. The sulphate requires a high temperature for its decomposition, and as in the case of the nitrate, the mineral acid set at liberty spoils the quality of the oil. Borate of manganese, otherwise excellent, has the disadvantages that the boric acid, not being volatile, remains in the oil. With the acetate the only drawback is the deep brown colour imparted by the decomposition products of acetic acid. All these faults are avoided by the use of oxalate of manganese, which is decomposed so readily that only a very slight heating with the oil is required to produce the desired effect. Generally 2—5 per cent. of oxalate is needed; rather more if the oil is to be kept at a very low temperature or is to dry rapidly. The mixture should be heated gently until the gases have escaped before being boiled.—A. R.

On the Preparation of Phosphorescent Sulphides of Calcium and Strontium. E. Becquerel. *Compt. Rend.* **107**, 892—894.

See under VII., page 117.

On the Chemical Constitution and Industrial Value of the Juice of Bassia Latifolia Roxb. E. Heckel and F. Schlagdenhauffen. *Compt. Rend.* **108**, 103—105.

This juice is a pale pink mass, hard at the ordinary temperature, but becoming soft when worked up. It loses nearly 60 per cent. of its weight of water at 105°. It was purified by agitation with hot water and dilute sulphuric acid, and then formed a soft sticky mass. When heated till all its water has been expelled it is brown, hard, and transparent, and after some days exposure to the air becomes covered with white patches, which dissolve in chloroform and carbon disulphide, but do not crystallise. Strong sulphuric acid colours it yellow and then brown, and a trace of ferric chloride develops in the mixture a fine red colour, becoming blue on standing, a reaction very similar to that yielded by cholesterol, but this substance is not present.

This gutta yields no picric acid when boiled with fuming nitric acid, and is not attacked by strong hydrochloric acid, aqueous potash, or fused potash. Its formula is $C_{25}H_{42}O$, and its ash is white, containing sodium chloride, and calcium phosphate and sulphate.

It could not be used as a substitute for ordinary gutta, but if mixed with an equal quantity of this latter it might be used for the vessels of galvanic batteries.—A. G. B.

PATENTS.

An Improved Paint or Coating. P. Molyneux, London. Eng. Pat. 6582, May 4, 1887. Amended November 13, 1888. 4d.

This amended specification describes a new paint for coating tanks in which mineral oil and turpentine are stored. It is composed of a solution of some resin insoluble in petroleum oil or turpentine, a little gum arabic and glycerin, together with some substance, such as litharge or other metallic oxide, capable of imparting body and permanence to the paint. The amendment consists in the withdrawal of the second claim relating to the mode of preparation of the paint. (This Journal, 1888, 392.)

—E. E. B.

Improvements in making Sulphide of Zinc. J. Wilson, Leith. Eng. Pat. 1546, February 2, 1888. 4d.

See under VII., page 119.

Improvements in the Production of Basic Lead Salts for Use as Pigments, and for other Purposes. F. M. Lyte, London. Eng. Pat. 2920, February 27, 1888. 6d.

BASIC sulphate or chloride or other basic salt of lead is converted into another basic compound of lead by treatment with a soluble salt, the acid of which is capable of combining with lead and forming the required compound. For example, basic lead sulphate may be converted into basic lead carbonate by treatment with a solution of sodium carbonate. The manufacture of basic sulphate of lead is described in previous patents, 10,298 of 1886, and 11,889 of 1886. (This Journal 1887, 601 and 732.)—E. E. B.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

PATENT.

Means for removing Lime from Skins, Kips, or Hides, and for Swelling or Puffing the same. J. Hauff, Feuerbach, Germany. Eng. Pat. 14,889, October 16, 1888. 4d.

AN aqueous solution of "creosotic acid" is used. The "creosotic acid" is recovered from the liquor by adding an equivalent of muriatic acid.—J. M. H. M.

XV.—AGRICULTURE, MANURES, Etc.

Occurrence of Solid Hydrocarbons in the Vegetable Kingdom. H. Gutzeit, Ber. **21**, 2881—2882.

THE author has found crystalline hydrocarbons in the fruit of the *Heracleum giganteum hort.* melting at 61°—63° and 66°—71°, and also in *Heracleum Sphondylium L.*, and in *Pastinaca sativa L.* They were found to possess the general formula C_nH_{2n} . The presence of similar bodies has more recently been pointed out by Abbot and Trimble. (This Journal 1888, 758.)—J. B. C.

Manurial Experiments with Concentrated Ox Manure.

N.N. Oesterreich. landw. Wochenblatt, **14**, 26—27.

COMPARATIVE experiments, with manure obtained from oxen fed mainly on refuse liquors of a spirit distillery (distillers' wash) and with animal charcoal superphosphate, were made with wheat, on a cold but humic clay soil, having a permeable sub-soil. The superphosphate yielded on the whole a product of better quality, but the ox manure produced heavier and more profitable crops. The same manure applied to turnips gave a better result than an equal weight (700 kilos. per 2.75 hectare) of potassio-ammonium-superphosphates. Unmanured crops were grown for comparisons in each case.—D. A. L.

Experimental Cultivation of Potatoes. Reymann, von Wichelhaus, Gascard and von Donat. *Der Landwirt (Silesia)*, **24**, 92.

FOUR comparatively new varieties of potatoes, Aurehe, Hermann, Odin, and Kornblume, were cultivated in four districts, some older varieties being grown in each district for comparison. In Zowade they were grown without manure side by side with Late Rose; in Heidehaus on freshly danged loamy humic sandy soil with Richter's Imperator; in Norok on fields near the Oder with Imperator, Flourball, Champion, Yellow Zwiebel; in Chmielowitz with Zwiebel and Charlotte. All the experiments suffered from drought. The largest crops were obtained in Norok, Zwiebel yielding 133.66; Hermann, 116.66;

Imperator, 108·33; Flourball, 100; Champion and Aurelie each 91·66 centners per morgen respectively, all the others yielded smaller crops, in Zowade none were above 50, in Heidehaus none exceeded 57·5, in Chmielowitz they varied from 47·61 to 71·73 centners per morgen. Of the new varieties only Hermann and Aurelie came up to the old ones in yield. Hermann is the richest in starch, having on an average 22·8 per cent. (this characteristic has been noticed by previous experimenters), whereas the poorest in this respect were Zwiebel with 19·6, Richter's Imperator with 18·5, Late Rose with 17·6 per cent. In the crops of Aurelie, Hermann, Odlin, Kornblume, and Zwiebel the tubers were much smaller than the original seed potatoes.

The following results were obtained under similar conditions in the field:—

Variety.	Ctr. per Morgen.	Percentage of Starch.
Aurora	65'	19·4
Champion	72'	22·6
Imperator	70·5	19·7
Zwiebel	72'	19·4

—D. A. L.

Experiments with Breisgau (Baden) and Russian Hemp. F. G. Stebler. Oesterreich. landw. und forstw. Woch. 13, 331—332.

The author made comparative cultivations of Breisgau and Russian hemp grown on similar soil under similar treatment. The crops were compared as to number, weight, length, and quality of plants. The Breisgau plants were

found far superior, yielding more uniform crops, with three times as many long spikes on an average 0·5 metre longer than the Russian, whilst the weight of the crop was more than double that of the Russian. Moreover, the individual plants were nearly twice as heavy, and the yield of hemp nearly three times as great, as that from the Russian crop. The stems of the Breisgau plants were more slender, smoother, and less branched than the Russian, and consequently the quality of the hemp was better.—D. A. L.

Thomas-Slag as a Manure. P. Bredt. Der Landwirt (Silesia), 24, 423 and 430—431.

The author has compared the fertilising value of Thomas-slag containing 80 per cent. of finely pulverised material and 20 per cent. of phosphoric acid, with dissolved, 18 per cent., Baker-guano. Various crops were grown in 1886, the soil being a wet sandy loam. The result with sugar-beet and oats were as follows:—Two plots of sugar-beet both received 2 centners of Chili saltpetre per morgen, and in addition, one had 4 centners of Thomas-slag, and yielded 143 centners of roots; whilst the other had 2 centners of Baker-guano, and yielded 131 centners of roots; the percentage of sugar being the same in the beet from both. Three plots of oats were grown. Each received $\frac{1}{2}$ centner Chili saltpetre when the seed was sown, and another $\frac{1}{2}$ centner 14 days after the plants appeared. The other manuring and results were as follows, numbers being per morgen:—without phosphate, 10·35 centners of grain; with 1 centner of Baker-guano, 11·70; with 2 centners of Thomas-slag, 11·90. Thomas-slag in these cases proved more efficient and economical than Baker-guano.

In 1887 more experiments were tried with peas, oats, and potatoes on a strong deep loamy soil, and sugar-beet on a heavy loam and on a slightly sandy soil. The manuring and results are given in the annexed table, the quantities being per morgen.

Plot.	Manuring.	Yield of							
		Peas.		Potatoes.		Roots.			
		Seeds.	Straw and Chaff.	Tubers.	Starch.	On Heavy Loam.		On Loamy Sand.	
						Roots.	Quotient.	Roots.	Quotient.
1	No phosphates.....	Centners. 10·8	Centners. 12·6	Centners. 133	Per cent. 20·3	Centners. 150·4	83·2	Centners. 81·6	83·8
2	10 lbs. of phosphoric acid as superphosphate.....	10·3	12·5	100	19·2	167·6	83·1	112·6	86·0
3	20 lbs. do. as Thomas-slag...	9·9	13·6	86	19·4	153·95	81·7	101·65	86·5
4	No phosphate.....	10·8	12·1	99	20·5	142·45	83·2	98·0	86·2
5	20 lbs. of phosphoric acid as superphosphate.....	11·25	12·8	126	20·5	189·45	84·8	114·90	86·3
6	10 lbs. do. as Thomas-slag...	11·35	12·6	108	19·0	187·33	83·4	147·9	86·7
7	20 lbs. do. as slag..... 10 lbs. do. as superphosphate }	12·50	14·3	87·8	20·1	175·30	84·4	126·4	86·0
8	20 lbs. do. as superphosphate	13·10	15·7	108·8	20·3	204·20	85·1	126·4	87·0

The quantities of phosphatic manures were doubled in the sugar-beet experiments. The results speak for themselves. With sugar-beet, however, it will be noticed, the soluble phosphate did best on the heavy soil, the slag on the light wet soil.—D. A. L.

Value of the Phosphoric Acid in Thomas-Slag as compared with that in Soluble Phosphates and in Bone-Meal deprived of much of its Lime. E. Heiden. Bied. Centr. 17, 798—800.

Four plots sown with oats and vetches received each 5 lbs. of nitrogen as Chili saltpetre, and three of them 25 lbs. of phosphoric acid, in addition, in the form of superphosphate, Thomas-slag, and bone-meal respectively. Two sets of

similar experiments were made on smaller plots. The total yields in kilos. for each experiment were as follows:—

	Large Plots.	Small Plots.	
		1.	2.
Without phosphoric acid	1245·78	126·91	119·52
Thomas-slag	1015·14	161·96	142·71
Superphosphate	1379·41	173·36	141·24
Bone-meal	1169·42	131·14	147·94

—D. A. L.

Manurial Experiments with Thomas-Slag. F. Far-ky.
Bied. Centr. **17**, 800—803.

HEAVY land, with northern aspect, was dressed on April 27 with Thomas-slag containing 18·95 per cent. of phosphoric acid; 85·17 per cent. passed through a $\frac{1}{4}$ mm. sieve. In one case slag was mixed with peat-dust. Two crops of oats were now taken, the first sown April—May and harvested September 1886; the second sown in April and harvested in August 1887, with the following results in kilos. per 10 square meters:—

Manuring.	1886.		1887.	
	Grain.	Straw.	Grain.	Straw.
None	6·815	11·893	4·871	11·275
0·4 of slag.....	7·473	15·112	5·435	11·393
0·4 of slag + 0·25 of peat	6·873	11·855	6·268	13·793
0·6 of slag.....	7·543	15·583	5·609	12·538
0·8 of slag.....	7·774	15·749	5·809	12·437
1·0 of slag.....	7·983	16·135	5·864	11·352

These results show the immediate and subsequent benefit derived from the dressings with slag. The peat was injurious the first season but beneficial the second, when it had undergone some change. Both the yield and the proportion of grain to straw are increased by the larger dressings of slag. Experiments on a larger scale were made with potatoes, manuring either with superphosphate containing 17·02 per cent. of soluble phosphoric acid, or with Thomas-slag, with or without peat-dust; and with a mixed fodder crop consisting of vetches, oats, barley, a few peas and maize, manuring with slag. The manures were sown on May 4, the potatoes on May 6, the fodder crop May 27.

the latter was harvested in August, the former in October; the results were as follows, numbers being kilos. per *ar*:—

Manuring.	Potatoes.		Per Cent.
	Large.	Small.	
None	52·30	21·69	17·2
None	55·33	22·02	17·1
11·314 of slag	52·14	22·29	17·3
5·074 of slag + 2·537 of peat-dust	73·53	19·25	17·3
2·537 of superphosphate.....	67·22	16·18	17·2

Mixed Crop.

Manure.	Mean Yield.
None	210
5·0 of slag	263
8·0 of slag.....	349·5

Showing beneficial action of Thomas-slag in both cases and in spite of late sowing.—D. A. L.

Hop-growing Soils in the Neighbourhood of Saaz in Bohemia. J. C. Lerner. Dingl. Polyt. J. **270**, 374—375.

THE soil on which the celebrated Saaz hops are grown is a diluvium composed of loam, clay, marl, and various kinds of sand. The appended analyses were made on samples of the soil of the hop gardens belonging to A. Dreher, at Michelob, near Saaz, which has apparently been formed by the disintegration of basalt rocks containing potash, soda, and lime feldspars. The hops grown here exceed even those known as "Stuttgart" in excellence.

In all, 10 samples were examined.

A.—MECHANICAL ANALYSIS.

Number of Sample.	Stones.	Coarse Gravel.	Medium Gravel.	Fine Gravel.	Coarse Sand.	Fine Sand.	Dust.
1	..	0·05	0·06	0·08	1·12	30·36	58·55

Absorptive silicates	12.36	12.08	12.68	11.25	11.03	10.84	10.98	11.14	10.03	16.04
Absorption capacity	90.8	104.0	94.6	78.2	80.0	108.4	86.0	75.4	85.4	90.8

* Omitted from total.

† Obviously a misprint; probably should be 0.80, in which case the total would be 8.58.

From these tables the excellent quality of the soils is apparent. They show a considerable loss on ignition, a high percentage of sesquioxides, a notable proportion of bases existing as absorptive silicates, and a marked absorption capacity, indicating a state of advanced disintegration, rendering them admirably suited for the use to which they are put.—B. B.

PATENTS.

Improvements in Manures. F. I. R. Seaver, London.

Eng. Pat. 571, January 13, 1888. 6d.

AN improved manure for preventing phylloxera, black rot, &c., and destroying insects, worms, &c., consisting of a mixture of the carbonaceous residue with the oil resulting from the distillation of Kimmeridge or other shale, and chalk, clay, or sand, together with 10 to 15 per cent. of superphosphate, and 5 to 10 per cent. of nitrate of soda. Sulphate of ammonia may be substituted for the nitrate of soda.—J. M. H. M.

Process of Converting Insoluble Phosphoric Acid contained in Mineral and Petrified Phosphates into available Phosphoric Acid. C. Glaser and C. F. W. Dambmann, Baltimore, U.S.A. Eng. Pat. 13,462, September 18, 1888. 4d.

THE ground phosphate is treated with phosphoric acid containing 40 per cent. by volume of phosphoric anhydride. In practice, the phosphoric acid may be extracted from one portion of the mineral and added to another portion; 50–130 parts of phosphoric acid are required per 100 parts of mineral phosphate.—J. M. H. M.

XVI.—SUGAR, STARCH, GUM, Etc.

Notes in Connection with the Manufacture of Starch.
H. Schreib. Zeits. f. angew. Chem. 1888, 694–696.

I.—Estimation of the Starch in various kinds of Grain, and Valuation of the latter for the Manufacture of Starch.

THE mere determination of the total amount of starch in a sample of grain is of little value, as no distinction is made between the insoluble and soluble starch, although the latter is useless if the grain is to be used for making starch. Also, the amount of gluten seriously affects the quantity of starch obtainable from the grain, for which allowance must be made in valuing the sample. Each part of gluten in rice causes the loss of an equal quantity of starch in the course of manufacture; consequently, a sample of rice containing 78 per cent. of starch and 4 per cent. of gluten would be more valuable than a sample containing 80 per cent. of starch and 8 per cent. of gluten, as 74 per cent. of starch could be obtained from the former and only 72 per cent. from the latter (the yield being found by deducting the percentage of gluten from the total starch in the sample). In the case of wheat the gluten is a valuable by-product, but in rice it is so difficult to separate from the starch, and when separated can only be sold for feeding or manurial purposes, that the less gluten the rice contains the more valuable it is. Owing to the difficulty in making accurate direct determinations of the starch in grain, the author prefers, in making an analysis of "broken rice," to estimate the gluten, ash, and moisture, and determine the starch by difference, after making a fixed allowance for the other non-starchy constituents of the grain, that is, fat, sugar, gum, and cellulose. The whole analysis by this method can be

finished in four hours, or considerably less time than is required for a direct estimation of the starch by the "inversion" method, and in the author's opinion the indirect estimation of the starch is quite as accurate as the direct. For the direct estimation, Lintner's process is preferred. As both's method for estimating starch by means of baryta (*see* this Journal, 1887, 608, and 1888, 77) not being considered reliable for all kinds of grain, the gelatinisation of rice, for example, being extremely difficult to effect.

The nature of the proteins is also of considerable importance in valuing rice, as the larger the proportion of them which are soluble in alkalis, and are consequently dissolved in the preliminary maceration of the rice with caustic soda, the less will there be to remove subsequently by mechanical means.

II.—Examination of Starch.

A weighed quantity of the starch is boiled with a definite amount of water till it is gelatinised, and the hot paste is then poured into a porcelain basin just large enough to hold it. When cold, it must be noticed whether the paste is solid or sufficiently liquid to run out if the basin be tilted. Wheat starch almost invariably contains free acid, and rice and maize starch free alkali. Either impurity upon prolonged boiling with the starch converts part of it into dextrin, and renders the paste liquid. The paste must not be boiled for more than one minute, and it is of importance to do this in a porcelain basin, as a metal one gives rise to lumps of non-gelatinised starch.—E. E. B.

PATENTS.

Improvements in or relating to the Production of Ammonia and Oxalic Acid and Alkaline Salts from Molasses or Desaccharised Lyes without Carbonisation. E. Meyer, Berlin, Germany. Eng. Pat. 17,317, December 10, 1887. 6d.

WHEN the molasses or concentrated lyes of the desaceharised molasses are heated with a large excess of caustic potash or soda, the greater part of the organic matter is destroyed; the nitrogen escaping as ammonia and amine bases in the gaseous form, which are collected and treated in well-known ways, while in the molten mass a considerable quantity of oxalates is formed, which can also be recovered.

The apparatus consists of a cast-iron still with head and receiver, and in this is first placed and heated the caustic alkali, from 8—20 times greater in quantity than the molasses to be treated, and, to ensure a regular and controllable evolution of ammonia, the molasses are gradually added.

"The molten mass in the retort when finished is run off, and a part of it is treated in any well-known manner for the purpose of separating oxalic acid, potash, and other salts. The greater part of the mass, however, returns to the process after having been rendered caustic."—W. M.

Improvements in Apparatus for filtering Saccharine or other Liquids or Solutions, and Appliances for cleaning the said Apparatus. B. E. R. Newlands, London, and J. Allott, Nottingham. Eng. Pat. 1392, January 30, 1888. 8d.

THE filtering apparatus consists of a series of frames or supports over which a filtering medium, such as a cloth, is stretched so as to leave a space between two opposite sides of such a medium. Each frame so covered with the filtering medium is called a "filtering member," and a complete filtering apparatus consists of a series of the "members" ranged side by side in a vessel or container in such a manner that any one "member" can be easily removed without disturbing the others. The apparatus can be used in either of two different ways. By the first method the liquid to be filtered is filled into the interior of these "members," and the clear liquor passes through the filtering medium into the containing vessel. By the second method the process is reversed, and the impure liquid being run

into the containing vessel, the clear filtrate finds its way through the medium into the separate "members."

Assuming the latter process to be used, it is essential that, on removing one of the "members" from the vessel containing the unfiltered liquor, for the purpose of cleaning the filtering medium, some provision be made for preventing the impure liquor getting into the pipe which connects the interior of the "member" with the pure liquor cistern. This is accomplished in four or five different ways, for a full description of which reference must be made to the specification and the drawings given therewith. The filtering medium or cloth may also be supported by arranging, inside or outside, according to the direction of the flow of the liquor, wire gauze or grids.

Adjoining the containing vessel is a tank containing water and two revolving brushes for cleaning the filtering medium or cloth. A travelling pulley arrangement is provided, by which any of the "filtering members" can be removed from the filtering apparatus to the cleaning vessel, and *vice versa*.—A. J. K.

Improvements in Apparatus for evaporating Saccharine or other Solutions or Liquids. A. Chapman, Liverpool. Eng. Pat. 1752, February 6, 1888. 11d.

THE efficiency of apparatus used for the evaporation of saccharine or saline solutions, whether by simple, double, or multiple effect, depends in a large measure upon the existence of a good circulation of the liquor contained in the pans. The author claims to have effected this end by the application of special arrangements of tubes to ordinary vacuum pans. For details the specification and drawings must be consulted.—A. J. K.

Improvements in Apparatus for evaporating Saccharine or other Solutions or Liquids. A. Chapman. Eng. Pat. 2511, February 20, 1888. 8d.

RELATES to the same subject as the above, with the addition of a description of a special method of removing the condensed water from the drum of the vacuum pan.

—A. J. K.

Improvements relating to the Refining of Sugar and to the Treatment of Syrup obtained therefrom. F. Bander, Paris. Eng. Pat. 16,397, November 12, 1888. 6d.

"THIS invention relates to an improved process of refining sugar by producing ozone by the joint application of steam and electricity."

The raw sugar is placed in a centrifugal machine which is closed by a hermetically-fitting cover provided with terminals for holding the conducting wires from suitable source of electricity, and carrying the poles by which the current is introduced into the interior of the machine.

Steam is introduced into the machine, and after the sugar is sufficiently moist the electric current is turned on whereby a constant succession of sparks is produced giving rise to ozone, which bleaches the sugar. The syrup which results from the action of the steam on the sugar, and is separated by the centrifugal action, can be mixed with fresh raw sugar and subjected to the same treatment.—W. M.

Improvements in Lixiviating Batteries for Raw Sugar or Sugar Mass. C. Steffen, Vienna, Austria. Eng. Pat. 16,703, November 17, 1888. 8d.

THIS invention "relates to improvements in lixiviating batteries for raw sugar or raw sugar mass, in which the lixiviation or washing of the sugar mass is effected by means of an aqueous, alcoholic, or other solution of sugar in a systematic manner, *i.e.*, by saccharine solutions of varying concentration," as described in Eng. Pat. 7119 of 1887. (This Journal, 1888, 41.)

For details, the specification and drawings must be consulted.—W. M.

XVII.—BREWING, WINES, SPIRITS, Etc.

Preparation of Wines from Fruits and Berries. Nessler. Bied. Centr. 17, 848—850.

Good and ripe fruit should be used; worm-eaten or bad fruit gives the wine a flavour and yields wine either difficult to clear or which will subsequently become turbid. The fruit may be crushed, or ground in a mill and immediately pressed. Pears often contain too little acid, but frequently mucic matter and much tannin, and therefore wines prepared from them are generally more difficult to deal with and not so good as wines prepared from apples and pears together. (See this Journal, 1888, 857.) With good, juicy, ripe fruit the best wine is obtained without the addition of water; but with unripe and very sour apples or very hard pears, it is best to press, mix the residues with water, and after some hours press again and mix the liquors. For every hectolitre of water used 10—12 kilos. of sugar are added; in cold weather the sugar is dissolved in warm water so as to bring the temperature of the must to 15°—20°. To prepare an ordinary house-wine 200 kilos. of fruit are used to one hectolitre of water and the necessary amount of sugar.

When the chief fermentation is over and most of the yeast has settled, the wine should be left to undergo a second fermentation, which makes it fit for keeping; if this fermentation do not set in of itself, and the wine be not thick, 1—1½ kilos. of sugar must be added, which then ferments.

Wines which are brown or black, or which become black or turbid, can be improved by mixing with 5—10 per cent. of good fresh yeast or with a litre of sweet skim milk or with ¼ litre of isinglass per hectolitre.

All berries contain too little sugar, and, with the exception of blackberries, too much acid.

The following table shows the proportion of sugar and acid in different berries, and the quantity of sugar and water required to make wine of different strengths:—

Fruit.	10 Litres of Juice or 11 Kilos. of Fruit require							
	Amount of		Litres	Kilos. Sugar.				
	Sugar.	Acid.		Water.	Ordinary Wine.	Good Table Wine.	Strong Liqueur Wine.	Wine.
Currants...	6.4	2.1	30	5.0	6.6	9	13	
Gooseberries	7.0	1.4	18	3.2	4.3	6	8.8	
Blackberries	4.0	0.2	0	1.0	1.4	2	3	
Bilberries...	5.0	1.7	24	4.2	5.6	7.6	11	
Raspberries.	3.9	1.4	18	3.2	4.3	6	8.8	
Strawberries	6.3	0.9	8	2.0	2.6	3.7	5.5	

Berries should be used soon after gathering, and if kept at all, they should be crushed, mixed with sugar, and protected from air. For the preparation of wine they may either be crushed or diffused; the latter plan is very suitable for currants. If fermentation do not set in within two days, the liquor is repeatedly run off and poured back into the vessel so as to bring it in contact with the air, and where possible wine-yeast should be added. If fermentation stop too soon, the yeast should be mixed up and wine-yeast or freshly-fermenting grape wine added. Fermentation is frequently sluggish in berry juices, but can be stimulated by adding 0.5—1 kilo. of washed and cut-up dried currants or raisins and a litre of water for each 0.5 kilo. added per 10 litres of juice or 11 kilos. of fruit. When crushed or soaked fruit is kept, either before or after fermentation, air

must be excluded, otherwise acetic acid will be formed. When the bottles are well filled and well corked, the top is dried and dipped into hot paraffin.—D. A. L.

Composition of Crab-apple Wine. F. Farsky. Bied. Cent. 17, 850—852.

WINE was prepared from waste crab-apples; they weighed 61 kilos. per hectolitre, and on an average 16.8 grains. each. The kernels were removed and 39.8 kilos. of the pulped fruit were mixed with 31.2 litres of distilled water and left in a warm room with frequent stirring for five days. The mass was now pressed, yielding 43.08 kilos. of must and 27.92 kilos. of pulp; the latter treated with water gave 10 litres of poor juice. The must contained 6.17 per cent. of sugar and 0.74 per cent. of malic acid (calculated); 3.8 kilos. of sugar were added and the whole left to ferment for nine days at 16°—20°. The new wine was stored in a vat in a cellar at 4°—8.3 C.; it was subsequently drawn off into small casks, and finally into ½ and ¾ litre bottles. The bottles were laid down for ½ of a year, when the wine was pronounced excellent by connoisseurs. It was analysed with the following centesimal results (specific gravity, at 17.5 = 1.00796), water, CO₂ and ethereal substances 88.976; alcohol (by weight) 6.999; grape sugar 0.551; cane sugar 0.0511; malic acid 0.469; acetic acid 0.026; nitrogenous matter 2.752; ash 0.165; not determined 0.01. The ash contained SiO₂ 1.394; Cl 9.697; sulphuric acid 9.030; phosphoric acid 2.788; K₂O 34.667; Na₂O 28.424; CaO 9.758; MgO 2.788; Fe₂O₃ &c. 3.636. After 13 months it contained 0.168 per cent. of malic and 2.067 of acetic acid. The poor juice from the press residue yielded 9.2 litres of vinegar containing 2.18 per cent. of acetic acid.—D. A. L.

On the Bitter and Resinous Constituents of Hops. M. Hayduck. Wochenschr. f. Brauerei, 1888, 328—337.

THE BITTER RESINS of hops exert a considerable influence on the development of various moulds. In order to obtain them, hops were extracted with ether in the cold. The residue obtained on driving off the ether was dissolved in 90 per cent. alcohol, and the solution thus obtained carefully treated with a lead acetate solution. The yellow precipitate (which is soluble in an excess of the precipitant) was washed, suspended in alcohol, and the lead removed by means of hydrogen sulphide. A resin remained in solution which the author calls the α -resin. Two further resins (β and γ) were obtained from the original alcohol solution, from which the lead precipitate had been removed, by distilling off the alcohol, taking up the residue with ether, shaking up this solution with dilute sulphuric acid (to remove ash-constituents), driving off the ether and treating the residue with petroleum ether of a low boiling point. A soft (β -) resin went into solution and a solid (γ -) resin remained behind. The α -resin is viscous and of a red-brown colour; it is almost odourless but intensely bitter. It dissolves easily in ether, alcohol, and chloroform. It is slightly soluble in cold water, more so in boiling water. An alcoholic solution gives a yellow precipitate with lead acetate, and a greenish-yellow precipitate with copper sulphate. An aqueous solution gives a white precipitate with the former and a bluish-white precipitate with the latter reagent. On boiling the resin with water for some time, or heating it on the water-bath, it is split up into several products of decomposition. Alcoholic lead acetate does not precipitate the β -resin, and copper acetate gives an emerald-green solution with it; in other respects its properties are identical with those of the α -resin. On standing for some time, crystals are developed both in the α - and the β -resin; those in the α -resin form long prisms and appear to be Lerner's acid; while those in the β -resin form rhombic plates. A mixture of these two resins is probably the bitter principle found in hops by Isleib and Greshof. They probably represent modifications of the acid of the hop-bitter principle. A third substance in the hops is the ethereal oil which later on forms the γ -resin. The latter is a brittle dark-brown substance, which is not bitter and does not dissolve in petroleum ether, but dissolves easily in alcohol and in ether. It forms compounds with

alkalis which are decomposed by acids. In its properties it resembles the resin obtained by the oxidation of hop-oil. If the aqueous solution be extracted with ether, the γ -resin is obtained as a solid orange-coloured mass on driving off the ether. The proportion of the three resins found in the hops was α -resin 4.7 per cent., β -resin 8.0 per cent., γ -resin 5.1 per cent. The first two are the important ones for brewing purposes. On boiling hops with four successive lots of 50 parts of water, treating the extracts with dilute sulphuric acid for the purpose of decomposing the salts, shaking up with ether and evaporating the ether extracts, four quantities of resin are obtained. The first three extracts contain about 3 per cent., the last about 1.5 per cent. of resin. The resin in each case was found to consist of the α -, β -, and γ -resins, and a modification of the first two produced by boiling. After this treatment, the hops were found to still contain 52.9 per cent. of total resin. The same hops might possibly therefore be repeatedly used in brewing without the extracts losing any of their bitter or antiseptic properties. The resins found in the aqueous extracts were also found in beer. During fermentation a portion gets eliminated from the wort. The aqueous hop extract rather assists than retards the development of yeast, aceties, and *narivule*. The lactic acid *pediococcus* is only slightly affected whilst the development of the lactic acid bacilli is considerably retarded. These antiseptic properties are entirely due to the α - and β -resins.—F. W. T. K.

Occurrence of Boric Acid in Wines. G. Baumert.
Ber. 21, 3290—3292.

THE presence of boric acid in a large number of samples of Californian wines was detected by the author three years ago, and he has since found it to occur in all the Spanish, French and Italian wines he has examined. Special attention has been given to the examination of the wines of Saxony and Thuringia, and boric acid has been detected, not only in the wine, but also in the leaves, tendrils, stalks, and berries of the vine at different periods of growth; the ash of the wine contains 0.2—0.4 grm. of boric acid, which was determined by the turmeric paper test. An examination of the vines and wines from the neighbourhood of Freyburg yielded similar results—boric acid was found in every case. Hence there seems to be no doubt that boric acid is a normal constituent of wines, and that it is derived from the soil, as shown by its presence in all parts of the vine. This has been confirmed by Ripper (Weinbau u. Weinhandel, 1888, No. 36) who has detected boric acid in 1,000 samples of German and other wines; and also by Soltsien (Pharm. Zeit. 33, 312).—C. A. K.

PATENT.

Process for the Preparation of Materials containing Starch for direct Treatment in Brewing Processes, the production of Malt, and other Saccharifying Processes. C. D. Abel, London. From E. Kiderleu and J. W. van Leenhof, Rotterdam, Holland; A. Wernike, Halle; and A. Wilhelmi and A. Köhlmann, Frankfurt, Germany. Eng. Pat. 1528, February 1, 1888. 6d.

THE raw material (fruits, cereals, &c.) contains, besides starch, a series of bodies such as fats, pectin bodies, oils, foreign kinds of saccharine matter, and bodies which form fusel oils, and these bodies are first removed by a process of extraction. In carrying out this process the raw material is coarsely ground and subjected in an extraction apparatus to the action of the extracting medium, which may consist of hot pure alcohol, alcohol vapour, benzine, or an aqueous solution of sulphurous acid. The extracting medium, mixed with the substances extracted, is then run off into a contiguous vessel, from which the extracting material may be distilled off and condensed again for future use. There remains in the extraction vessel the residue of the raw material, consisting of the starch, the cellulose constituents, and such albuminous bodies as are insoluble in the extracting medium. This mixture, which still contains some of the extracting medium, is run off into the saccharifying vessel, the extracting medium distilled off and condensed, and the residue, after treatment with hot water, saccharified by malt in the usual way.—A. J. K.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A)—CHEMISTRY OF FOOD.

PATENTS.

Improvements in or connected with Apparatus for Preserving Milk. W. C. Hallett, London. From K. G. Dahl, Drummen, Norway. Eng. Pat. 14,113, October 1, 1888. 6d.

THIS specification describes apparatus for carrying out the improved process for sterilising milk, described in Eng. Pat. 10,903, of 1886. (This Journal, 1887, 377.) C is a strongly braced angle-iron frame arranged to hold the sterilising vessels *u*. D is a tank in which the heating and cooling is effected by the steam pipe F'. G is a lifting arm fixed to a vertical hydraulic lifting ram by means of which the sterilising vessels are lowered into a receiver from the tanks.

(B)—SANITARY CHEMISTRY.

PATENT.

Improvements in the Purification of Sewage and Impure Waters. A. J. Capron, London. Eng. Pat. 1161, January 25, 1888. 8d.

THE sewage is passed continuously through a vessel containing a number of iron discs set on a horizontal revolving shaft; the space between each pair of discs is partially filled with sand or other abrasive material. The upper part of the periphery of each disc is in contact alternately with the opposite terminals of a galvanic battery, dynamo, or other source of electric current. Decomposition of the water sets free oxygen, which will "completely oxidise all the metallic iron taken up in solution." The abrasion of the sand keeps the surfaces of the discs clean.—C. C. H.

(C)—DISINFECTANTS, &c.

PATENTS.

Improvements in Means for Effecting the Evolution of Sulphurous Acid for Disinfecting and Deodorising. J. Hanlon, Wakefield. Eng. Pat. 1393, January 30, 1888. 4d.

A SULPHITE, such as "alkali waste in which the sulphur compounds have been oxidised into sulphite," or a bisulphite is mixed dry with a soluble acid sulphate, or bisulphate, e.g., those of soda or potash; such a mixture when used gives off sulphurous anhydride. A substance, such as Kieselguhr or fossil meal, may be saturated with sulphuric acid and used in place of the bisulphate.—C. C. H.

Improvements relating to the Preparation of Carbolic Acid and to the Formation thereof into Lozenges or the like. O. Rademann, Forbach, Germany. Eng. Pat. 1163, January 31, 1888. 4d.

WHEN carbolic acid is melted in a water-bath, cooled quickly, and stirred it is obtained as small crystals. These are mixed intimately with 10 per cent. of pure boracic acid, and the snow-like mass pressed into lozenges or cakes. By this means the acid is obtained in a form easily transported and handled without danger to the skin; moreover its melting point is considerably raised and as its solubility is very largely increased, an antiseptic solution of a definite strength can therefore be readily prepared.

—C. C. H.

Improved Manufacture or Preparation of Antiseptics. W. Black, Newcastle-on-Tyne, and W. L. Rennoldson, Jarrow-on-Tyne. Eng. Pat. 1696, February 4, 1888. 6d.

AN easily soluble salt, e.g., sulphate or chloride of sodium, or chloride or sulphate of aluminium, zinc, or iron, is recrystallised, and obtained in a finely granular condition. Upon the dry salt from 2 to 4 per cent. of perchloride of mercury solution is sprinkled and the mixture dried at from 60° to 70° F.—C. C. H.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Examination of Sulphonal. Kobbe. Pharm. Zeit. 1888, 739.

IN the manufacture of sulphonal some difficulty is experienced in preparing an odourless product. According to the author, it is easy to determine whether a preparation is odourless or not by boiling 1 grm. with about 10 cc. of water in a test tube, when any remaining odour is easily detected.—F. W. T. K.

On the Physiological and Therapeutic Importance of Creatine. Kobert. Chem. Zeit. 12, 1662.

THE physiological action of creatine is still far from settled. Some physiologists look upon it as a waste product and as valueless to the muscles; others again as an important muscle-strengthening agent. The writer adheres to the latter view. Experiments of his have led him to the conclusion that creatine exerts a very beneficial influence on muscular activity and that, accordingly, meat broths are not only pleasant appetisers but important muscle-strengtheners. Kobert has experimented with numerous other substances, but so far hypoxanthine and caffeine are the only ones which exert an influence similar to that of creatine. Lehmann has pointed out that the above action of creatine would explain the invigorating properties of Liebig's extract. J. Mays has further shown that solutions of creatine and creatinine excite an exhausted heart, and hypoxanthine and xanthine behave similarly, but on the other hand other meat constituents do not have such an effect. Creatine is a substituted guanidine, and Baumann and Gergens have shown that the latter is a specific though practically useless and dangerous muscle-irritant. Kobert further holds that creatine has important digestive properties, increasing the activity of the smooth muscles of the stomach and the intestines. For therapeutic purposes he therefore recommends 0.1 grm. of creatine taken 4 to 6 times daily; (1) for increasing the activity of the muscles in cases of weakness; (2) in cases of weak heart; (3) in chronic weakness of the digestive organs. The dry powder is placed on the tongue and washed down with water. Liebig's extract freed from salt crystals exerts a similar action, but the gelatins in it have an injurious influence in intestinal disorders.—F. W. T. K.

Conversion of Terpine into a Menthe. G. Boucharlat and J. Lafont. Compt. Rend. 107, 916—918.

WHEN terpine $C_{10}H_{16}$, 2 H_2O is heated to 100° for 15 hours with an aqueous solution of HI (saturated with this gas at 0°) the dihydriodide of terpine crystallises out, identical with the corresponding terebenthene derivative, $C_{10}H_{16}$, 2 HI. On raising the temperature the crystals melt, iodine is liberated, and the principal product formed is menthyl-dihydriodide $C_{10}H_{19}I$ or an isomeride of the same. The oily mixture, after removing excess of acid, is heated to 100° with alcoholic potassium acetate, and the filtrate treated with water. The oil which separates is distilled, the portion going over from 167°—170° being collected separately. The formula of the substance in this fraction is $C_{10}H_{18}$. It fixes the halogen acids slowly, which feature distinguishes it from the terpine $C_{10}H_{16}$. The solid hydrochloride $C_{10}H_{18}$, 2 HCl melts at about 50°. The mono-hydrochloride is also described. Alkalis act on it, reproducing the hydrocarbon $C_{10}H_{18}$. Its composition is the same as that of menthol hydrochloride, obtained by the action of HCl on menthol $C_{10}H_{20}O$, or on menthol camphor. The author concludes from the above that natural menthol must be regarded as belonging to the terpine series.—A. R.

A New Commercial Process for the Preparation of Cocaine. C. Liebermann and F. Giesel. Ber. 21, 3196—3202.

THE extract of coca leaves does not yield pure cocaine directly, but a mixture of a large number of alkaloids, from which the cocaine is separated. Liebermann has lately unfolded the nature of one of these by-products, to which he gave the name of isotropyl cocaine, because the benzoic acid of cocaine is replaced in it by isotropic acid (γ and δ). All these foreign alkaloids are easily split up by boiling with hydrochloric acid into ecgonine, and this fact is made use of for preparing ecgonine on the large scale. The amorphous by-products up to this time also valueless, are to be had in quantity. Ecgonine forms the starting point for the preparation of cocaine. Thus, ecgonine is converted into the benzoyl derivative, benzoyl ecgonine, and the latter is decomposed so as to yield cocaine by Einhorn's method (this Journal, 1888, 228). The cocaine thus prepared from

the hitherto troublesome by-products above referred to, shows all the chemical, physical, and medicinal properties of the "natural" cocaine.—S. H.

"*Imperialine*," a new Alkaloid. K. Fragner. Ber. **21**, 3284—3287.

Frittelaria or *Coronaria imperialis* (*Crown Imperial*), which was formerly employed for medicinal purposes, contains a poisonous alkaloid which the author names *Imperialine*. It is best obtained pure as follows:—The crushed bulbs are pulverised with lime, the mixture heated on the water-bath until perfectly dry, and then extracted with chloroform. The extract is shaken with dilute tartaric acid, the alkaloid precipitated from the acid solution with sodium carbonate, the precipitate washed and recrystallised from alcohol. The yield is 0.08—0.12 per cent.

Imperialine, $C_{35}H_{60}NO_4$, crystallises in colourless needles, is very readily soluble in chloroform, and moderately soluble in ether, benzene, amyl alcohol, light petroleum, and alcohol, but only very sparingly in water. Its solutions have a bitter taste, and the physiological action of this alkaloid is similar to that of *Scilla maritima*. When heated to 240° it turns yellow, becomes brown at 248°, and melts completely at 254°. Its specific rotatory power in chloroform solution is $\alpha_D = 35.40$.

The hydrochloride, $C_{35}H_{60}NO_4 \cdot HCl$, is crystalline, and readily soluble in alcohol and water. The platinochloride, $(C_{35}H_{60}NO_4)_2 + 11PtCl_6$, and the aurichloride, $C_{35}H_{60}NO_4 + HAuCl_4$, do not crystallise very readily. The sulphate is very hygroscopic, and the oxalate crystallises only from very concentrated solutions. Solutions of the salts give precipitates with most of the usual reagents for alkaloids, and the free base gives the following characteristic reactions:—When treated with concentrated sulphuric acid it turns slightly yellow, but when previously mixed with sugar it gives a yellowish-green colouration which passes through pale brown, flesh-colour and cherry-red, and, after standing for a long time, finally becomes dark violet. It is coloured slightly green when treated with Froehde's reagent, and with Mandelin's reagent it gives an olive-green colouration which, passing through reddish-brown, turns dark brown. When mixed with sulphuric acid and then treated with potassium nitrate or chlorate it gives an orange colouration, but if previously warmed a dark reddish-yellow colour. It turns yellow when warmed with nitric acid; when treated with hydrochloric acid the solution, which is strongly fluorescent, becomes brownish-green on warming and finally changes to brownish-red.

—F. S. K.

Action of Acid Chlorides on Ecgonine Methyl Ether Hydrochloride. A. Einhorn and O. Klein. Ber. **21**, 3335—3338. (Compare pp. 131—133.)

COCAINE can be prepared by converting ecgonine into the methyl ether and treating the latter with benzoyl chloride.

Ecgonine methyl ether hydrochloride—

is obtained by passing anhydrous hydrochloric acid into a methyl alcoholic solution of ecgonine hydrochloride until the solution has become cold, and then heating the mixture for about an hour with inverted condenser. After evaporating, the salt can be isolated either by adding sodium carbonate, extracting with ether and converting the product into the hydrochloride, or by allowing the salt to crystallise from the concentrated alcoholic solution. It crystallises from dilute alcohol in prisms with 1 mol. of H_2O , and melts at 212° with decomposition.

Cocaine can be obtained by heating a mixture of equal weights of the preceding compound and benzoyl chloride on the water-bath until the whole becomes homogeneous, and the evolution of hydrochloric acid ceases. The hot melted mass is then poured into water, separated from the precipitated benzoic acid, and the cocaine precipitated with

ammonia or alkaline carbonates, and recrystallised from alcohol. The cocaine thus prepared shows all the properties of the natural alkaloid.

Isovalerylecgonine methyl ether—

was obtained in the form of an oil by heating a mixture of equal weights of ecgonine methyl ether hydrochloride and isovaleryl chloride at 100° for about 15 minutes and precipitating the product with sodium carbonate. The hydrochloride, hydrobromide, and hydriodide are crystalline. The platinochloride, $(C_{15}H_{25}NO_4)_2 \cdot H_2PtCl_6$, crystallises in large plates.

Phenylacetylecgonine methyl ether—

obtained by treating phenylacetyl chloride with ecgonine-methyl-ether hydrochloride as described in the case of cocaine, is an oil. The hydrobromide, hydriodide, and platinochloride, $(C_{18}H_{23}NO_4)_2 \cdot H_2PtCl_6$, are crystalline.

Orthophthalglydi-ecgonine dimethyl ether, $C_{25}H_{36}N_2O_8$, prepared in a similar manner is a crystalline substance which has a similar physiological action to that of cocaine.

The platinochloride, $C_{25}H_{36}N_2O_8 \cdot H_2PtCl_6$, crystallises from water, and the hydriodide from alcohol in plates.—F. S. K.

Cinnamylecgonine. C. Liebermann. Ber. **21**, 3372—3376.

Cinnamylecgonine, $C_{19}H_{17}(C_9H_7O \cdot NO_2)$, can be prepared by heating ecgonine with cinnamic anhydride and water (see also pp. 131—133). After keeping the mixture overnight it is triturated with 6—8 times its weight of water, the cinnamic acid and unchanged anhydride separated and the remainder of the acid extracted with ether. When the aqueous solution is evaporated it solidifies to a mass of crystals and a second crop can be obtained by concentrating the mother-liquor. The yield is about 60 per cent. of the ecgonine employed. It melts at 216° with decomposition, and is readily soluble in alcohol, but is reprecipitated on adding ether. It is decomposed into ecgonine and cinnamic acid when boiled with hydrochloric acid, and when treated with cold, dilute potassium permanganate it is immediately oxidised, the smell of benzaldehyde being perceptible.

Cinnamylecgonine, $C_9H_{13}(CH_3)(C_9H_7O)NO_2$, is obtained when anhydrous hydrochloric acid is passed into a concentrated methyl alcoholic solution of cinnamylecgonine. The yield is about 50 per cent. It forms large colourless crystals, melts at 121°, and is almost insoluble in water, but readily soluble in most of the usual solvents. When boiled with hydrochloric acid it is readily and quantitatively decomposed into ecgonine and cinnamic acid. The hydrochloride is precipitated when a large volume of ether is added to a concentrated alcoholic solution containing a little hydrochloric acid; it separates in an oily condition but solidifies after some time. When treated with cold potassium permanganate it is immediately oxidised and the solution then smells of benzaldehyde. The platinochloride, $(C_{19}H_{23}NO_4)_2 \cdot H_2PtCl_6$, crystallises in microscopic needles melting at 217°.

The smell of benzaldehyde which is noticed in the oxidation of natural cocaine seems to indicate the presence of cinnamylecgonine.—F. S. K.

Ergosterin, a new Proximate Constituent of Ergot of Rye. C. Tanret. Compt. Rend. **108**, 98—100.

This substance is very similar to cholesterol; the rye containing ergot is exhausted several times with alcohol, the solution distilled, and the residue extracted with ether; when the ether is evaporated, an oily mass containing slender crystals is obtained. The crystals are picked out and recrystallised, first from slightly alkaline alcohol, to saponify adhering oil, and then from pure alcohol; the yield is about 0.02 per cent.

Ergosterin has the formula $C_{26}H_{40}O \cdot H_2O$; it crystallises in slender needles which lose their water of crystallisation at 110°; it melts at 154°, and boils, under 20 mm. pressure, at 185°; is soluble in 500 parts of cold and 32

parts of boiling alcohol, in 80 parts of cold and 38 parts of boiling ether, and in 45 parts of cold chloroform. Its specific gravity when it has been melted is 1.04; it oxidises slowly in air at the ordinary temperature, very rapidly at 100°, becoming coloured and odorous, but is not attacked by boiling concentrated alkali. It is a monatomic alcohol, and forms an acetate, $\text{CH}_3\text{COO}(\text{C}_{26}\text{H}_{50})$, which crystallises in nacreous anhydrous spangles, which are insoluble in water and difficultly soluble in cold alcohol; they melt with some decomposition at 169°. The author has also obtained the formate and butyrate.

Ergosterin may be distinguished from cholesterol by the fact that it dissolves entirely in sulphuric acid, and that chloroform, shaken with the solution, does not become coloured as it does in the case of cholesterol.—A. G. B.

PATENTS.

Improvements in the Treatment of Amorphous Alkaloids obtained in the Preparation of Cocaine. C. Liebermann and F. Giesel. Eng. Pat. 12,179, August 23, 1888. 6d.

THE amorphous alkaloids are decomposed by boiling with an excess of hydrochloric acid (sp. gr. 1.1 to 1.2) for 1–2 hours. The hydrochloride of eegonine in solution is filtered from the insoluble organic acids, the solution evaporated to dryness, and the free base obtained by treating with alkali. The eegonine thus obtained may be converted into benzoyl eegonine by treating with benzoyl chloride or benzoic anhydride, as follows:—

An aqueous solution of eegonine (1 mol.), saturated at boiling point, is treated with rather more than an equivalent quantity of benzoic anhydride (1 mol.). To complete the reaction, the mixture is maintained for $\frac{1}{2}$ –1 hour at the boiling point. The benzoic acid produced is removed with ether. The aqueous solution contains the benzoyleegonine, which crystallises on shaking or standing. (Compare pp. 131–133.)—J. B. C.

Improvements in Extracting Perfumes from Flowers, Fruits, and other Substances containing Etheral Oil or Aromatic Matters, and Apparatus therefor. W. P. Thompson, Liverpool. From G. D. Nellensteyn, Amsterdam, Holland. Eng. Pat. 15,299, October 24, 1888.

THE apparatus employed is shown in the accompanying figure.

A is a reservoir, of sufficient strength to resist external pressure and made of iron or any other suitable material, which can be opened and hermetically closed. This reservoir is connected with a receiver B by means of a pipe a, provided with a cock or valve b. The receiver B is placed in a cooling vessel C, containing a freezing mixture. The receiver B can also be opened and hermetically closed, and is connected to a chamber D by a pipe c. This chamber D is provided with several layers of vaselin, suet, or any other substance fit to absorb aromatic substances placed on the perforated or other shelves shown. The chamber D is connected by a pipe d to an air-pump E, or any other arrangement in order to produce a vacuum. The operation is as follows:—The reservoir A is filled with flowers, &c., and closed hermetically; the air is then pumped out from the reservoir A, the receiver B, and the chamber D. By the influence of the vacuum and the low temperature

in the receiver B, the volatile oils are therein condensed, either in the liquid or solid state, to be afterwards removed. By passing the air, when being pumped out, over vaseline or suet in chamber D any volatile matters which have not condensed in B are retained.—J. B. C.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

PATENTS.

Improvements in or relating to the Production of Pictures or Images on Materials or Fabrics having a Dark Ground by a Photographic process. W. P. Thompson, Liverpool. From J. W. C. C. Schirn, Breslau, Germany. Eng. Pat. 1026, January 23, 1888. 6d.

AN application of ordinary transfer methods to the production of light-coloured images on a darker ground, after the manner of Limoges enamels.—C. H. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

PATENTS.

Improvements in Explosive Compounds. A. V. Newton, London. From A. Nobel, Paris, France. Eng. Pat. 1469, January 31, 1888. 6d.

THIS explosive mixture consists preferably of charcoal, nitrate of baryta, and pierate of ammonia or amorphous phosphorus. The two last ingredients are added in order to counteract the slow combustion inherent to nitrate of baryta powders.—C. N. H.

Improvements in the Manufacture of Safety Fuses. A. V. Newton, London. From A. Nobel, Paris, France. Eng. Pat. 1470, January 31, 1888. 6d.

INSTEAD of meal powder, which now forms the combustion core of safety-fuses, the inventor proposes to use a cellulosidal substance made in the following manner:—To 100 parts (by weight) of nitroglycerol, 15 to 20 parts of camphor are added, and the solution thus obtained is thickened, by dissolving in it 6 parts of nitrated pulped cotton. To the above are added 70 parts of chlorate of potash, 25 parts of ferricyanide of potassium, and 44 parts of nitrated soluble cotton. These, when thoroughly incorporated, produce a substance of the consistency of soft india-rubber and easily workable into thread.

The advantages claimed are "absolute continuity, imperviousness to moisture," and absence of smoke when ignited.—C. N. H.

XXIII.—ANALYTICAL CHEMISTRY.

Apparatus for Fractional Distillation in a Partial Vacuum.
J. W. Brühl. Ber. 21, 3339-3342.

For fractional distillation in a partial vacuum the author recommends the following apparatus, a diagram and description of which are given below:—

Fig. 1.

A is a glass cylinder connected at *a* with the vacuum apparatus, and provided with a ground edge, on which rests the glass cover B. The tube *c*, which is connected with the distilling apparatus, passes through an india-rubber cork fitting tightly into the tubulure *b*. A glass rod, *c*, provided with a handle, passes through an india-rubber cork tightly fitted into the tubulure *d*, almost to the bottom of A, and at a short distance from the lower extremity is pierced with a hole, in which is pressed a pin *i* (Fig. 2). *f*, *g*, *h*, consist of a hollow stem *f*, to which the discs *g* and *h* are attached; it is made of ebony, and can be fastened on to *c* by means of a bayonet-shaped catch.

Fig. 2.

Test tubes having been placed in the holder *f*, *g*, *h*, the rod *c*, to which the cover B is attached, is fitted into the stem *f*: the two portions made fast by means of the catch are placed in A, and the apparatus made air-tight by pressing the greased edges of A and B together. The distilling vessel is then made air-tight, *a* is connected with the vacuum apparatus, and the distillation proceeded with; by turning the rod *c* the receiver can be changed at will. It is inadvisable to move the india-rubber stoppers after they have once been placed in position, but when the central one requires replacing, the pin in the glass rod can be easily removed.

The air-bath (Fig. 3), can be advantageously employed for all distillations.

Fig. 3.

The flask is suspended in a hemispherical metal basin so that it does not touch the bottom or sides, and is covered by an asbestos cone, which is provided with a radial slit and a circular opening to admit the neck of the flask. The temperature can be regulated and kept constant quite as easily as when a water, oil, or any other liquid-bath is employed. For high temperatures, the metal reflector shown in Fig. 3 is fixed on the Bunsen lamp.—F. S. K.

Hampe's Method of determining Cuprous Oxide in Metallic Copper. F. F. Dewey. Eng. and Min. Jour. 46, 460-461.

The above method—which consists in treating the sample with a cold solution of neutral nitrate of silver for three or four days, estimating the copper in the residue, and calculating from this the cuprous oxide on the assumption that two-thirds of it was transformed into an insoluble basic nitrate, and that the other third had gone into solution—was found to give unsatisfactory results with coppers containing excessive amounts of Cu_2O . The paper gives the results of a few experiments carried out to ascertain what really takes place.

A material was prepared from electrolytic copper having the following composition:—

	Per Cent.
Cu	83.317
Cu_2O	16.670
Fe	60.013
	<hr/> 100.000

The above figure for Cu_2O was calculated from the oxygen obtained by difference. Some of this metal was submitted to Hampe's treatment and the result multiplied by the Hampe constant, when 24.44 per cent. of Cu_2O was obtained, whereas if it be considered that the whole of the Cu_2O in the metal is converted into insoluble nitrate the resulting figure would be 16.29 per cent. of Cu_2O . Similar experiments were conducted on the same material diluted with pure copper and in which the percentages of Cu_2O were 13.33 and 9.75; when 12.455 and 9.10 respectively were the figures obtained, assuming as before that the whole of the Cu_2O becomes insoluble. The author gives an equation for the reaction which takes place, and concludes from these results, where the amounts of Cu_2O are rather high, that "when copper containing Cu_2O is treated with a neutral solution of AgNO_3 in excess in the cold, all the Cu_2O is converted into the insoluble basic nitrate."—A. W.

Table for Estimating amount of Nitric Acid from observed volume of Nitric Oxide. A. Baumann. Zeits. f. angew. Chem. 1888, 662-664.

The increasing use of gasometric processes for the estimation of nitric acid induced the author to compile a table to facilitate the calculation of results.

The table gives the value of $b \times 2.4134$
760 (1 + 0.00366 t)
where b = barometric pressure in mm.

t = temperature.

2.4134 = weight of N_2O_5 in milligrammes corresponding to 1 cc. of NO at the normal temperature and pressure.

If the gas be measured moist, the tension of the aqueous vapour, at the particular temperature, must be deducted from the barometric reading. Also, to allow for the expansion of the mercury in the barometer, deduct from the observed pressure, 1 mm. for temperatures of 10° to 12° , 2 mm. for 13° to 19° , 3 mm. for 20° to 25° C.

The number of cc. of nitric oxide obtained, multiplied by the coefficient obtained as above, gives the weight in milligrams of nitrogen pentoxide.—E. B.

Titration of small Quantities of Gases in Mixtures of Gases. P. Behrend and H. Kast. *Dingl. Polyt. J.* **270**, 423—435.

The technical methods employed for the estimation of small quantities of gases in mixtures do not allow of the determination of amounts less than 0.5 per cent., and even then it is necessary to employ a large quantity of the mixture, as, for instance, in Pettenkofer's method for the estimation of carbon dioxide, &c., using Hesse's apparatus, when $\frac{3}{4}$ to 1 litre is required. Bunte has recently proposed a method for the volumetric estimation of small amounts of gases in mixtures by means of his (Bunte's) burette, where the quantity of gas employed is only 100 cc., and by means of which 1 per cent. of a gas can be determined (*Dingl. Polyt. J.* **269**, 232). The method applies to the determination of sulphuretted hydrogen, ozone, ammonia and sulphur dioxide. The authors have examined the method as regards the first two of the above gases.

1. *Determination of sulphuretted hydrogen*—100 cc. of the gaseous mixture are measured off into a Bunte's gas-burette in the usual manner, the remainder of the water in the measuring tube run out to the lower mark of the tube, and then an iodine solution added gradually until the colour of the solution, which disappears rapidly at first, remains of a yellow tint. During the addition of the iodine solution the contents of the tube are well shaken from time to time; the iodine solution should contain 1.134 grms. of iodine per litre, when 1 cc. = 0.1 cc. sulphuretted hydrogen. Sulphur separates during the reaction according to the equation, $\text{H}_2\text{S} + \text{I}_2 = 2 \text{HI} + \text{S}$, and the turbidity formed aids in discerning the end reaction, or a few drops of sodium bicarbonate and thin starch paste may be added before introducing the iodine solution, whereby the end reaction (formation of the blue iodide of starch) is more easily observed. A small volume of the iodine solution, taken as 0.2 cc. in the authors' experiments, remains at the bottom end of the measuring tube, and does not come in contact with the gas; this volume of solution is subtracted from the amount used in each case. The method was employed for the determination of the sulphuretted hydrogen in a mixture of this gas with coal gas, the results being checked gravimetrically by passing a weighed volume of the gas through an acetic acid solution of lead acetate and again weighing it. The following results were obtained:—

Per Cent. of Sulphuretted Hydrogen.		Difference.
Gravimetrically.	Bunte's Method.	
1.34	1.33	0.01
1.29	1.19	0.10
1.29	1.22	0.07
0.67	0.62	0.05
0.58	0.58	0.00
Mean difference.		0.04

The above results by Bunte's method, which are corrected for temperature and pressure, are the mean, in each case, of several closely agreeing results. Equally accurate results were obtained with a mixture of sulphuretted hydrogen, coal gas, and air; the iodine-solution was, in this case, diluted to half the strength given above.

The authors have employed this method to determine the sulphuretted hydrogen in coal gas as the gas leaves the retorts, the samples being taken from the ascension pipes by means of a suitable pump. The appended table shows the percentage of sulphuretted hydrogen in the crude gas from I. Saar coal; II. Bohemian brown coal; III. Tyne Boghead Cannel, at short intervals during the distillation:—

Time of taking Sample.		Per Cent. of Sulphuretted Hydrogen in Crude Gas from:—		
Hour.	Minutes.	I.	II.	III.
1st	5	1.19	3.75	0.74
	15	0.98
	20	0.30
	25	..	3.23	..
	35	1.03	..	1.10
	45	..	3.00	..
	55	1.01	..	0.79
	65	0.73	2.02	..
2nd	70	0.85
	80	0.81	1.50	..
	85	0.41
	95	0.62
	100	0.58
	105	..	1.95	..
	110	0.80
	115	0.71
3rd	125	0.47	0.51	..
	130	0.68
	140	0.40	0.51	..
	145	0.44
	160	0.38	1.00	0.52
	170	..	0.72	..
	175	0.31	..	0.38
	185	..	0.60	..
4th	190	0.54
	195	0.46
	200	..	0.63	..
	205	0.38	..	0.46
	210	..	0.64	..
	220	0.21	0.43	0.10

These results show that the maximum percentage of sulphuretted hydrogen in the crude gas is, in the cases of Saar and Bohemian brown coal, immediately after charging; also that the latter contains almost three times as much as the former. The maximum amount of the gas from Tyne Boghead Cannel takes place about 35 minutes after charging.

It is remarked that a similar use may be made of Bunte's method for examining coal gas at different stages of its manufacture.

2. *Determination of Ozone*.—To determine ozone in ozonated oxygen, a measured volume of the gas is treated in a Bunte's burette with a solution of potassium iodide (about 7 cc. of a solution containing about 17 grms. of potassium iodide per 100 cc.) and then very dilute sulphuric acid added until the liquid reaches to the 10th graduation on the measuring tube. The contents of the tube are well shaken and the separated iodine titrated with $\frac{\text{N}}{20}$ or $\frac{\text{N}}{50}$ sodium thiosulphate, which is gradually added to the contents of the burette. From the amount of thiosulphate solution used the quantity of iodine separated, and therefore the percentage of ozone is found.

The authors are investigating similar methods of Bunte in regard to the determination of other gases.—C. A. K.

On the Accuracy of the Dry Assay for Silver. Dingl. Polyt. J. 270, 468—471.

A. GÖRZ (Berg- und Hüttenmännische Zeitung, 1888, 441), and H. ROSSLER (this Journal, 1888, 869) agree that for the assay of argentiferous materials the use of the scorifier is preferable to that of the crucible (unless special circumstances have to be considered, such as the presence of carbonaceous matter or the fact of the ore under treatment being a very poor one) as it gives results which are higher and nearer the truth.

In 100 grms. of crucible-slag, Görz found 2 and 4 mg. of silver in two different samples, and is of opinion that no sensible loss occurs in scorification, the chief amount of deficit being due to the subsequent cupellation. Nevertheless silver is present in scorifier slag, 100 grms. of it yielding 16.5 mg. of silver in the case of a rich ore, and 2.5 mg. in that of a poor one, corresponding to 0.25 and 1.04 per cent. respectively of the total silver present in the sample.

The loss of silver during cupellation is due both to absorption in the cupel and volatilisation, and increases, as would be expected, with the proportion of lead, and the temperature used.

In used cupels were found: in 100 grms. that had been used in the assay of a rich ore, 43 mg. of silver, corresponding to 0.5 per cent. of the total silver, and in the same quantity used for a poorer ore, 2 mg., equivalent to 1.5 per cent. of the whole.

Further, 580 mg. of silver were found in 100 grms. of the flue-dust of a gas-muffle.

The appended table shows the mean results of a large number of assays made on mixtures of known composition, and indicates what loss may be expected even when, as in this case, the utmost care is exercised, and the cupellation conducted at the lowest possible temperature.

Even here the loss appears smaller than is really the case, for the buttons of silver obtained by cupellation are never quite pure, but always contain some tenths of a per cent. of lead, and frequently copper and bismuth as well. It suffices to dissolve a few grms. in nitric acid and supersaturate with ammonia (a white precipitate of lead and bismuth hydrates, and a blue colour due to the copper being formed) in order to demonstrate this.—B. B.

Quantitative Analysis by Electrolysis. A. Classen and R. Schelle. Ber. 21, 2892—2899.

The author has employed for purposes of electrolysis two accumulators of the following dimensions. Each contains six negative and five positive lead plate electrodes 6 mm. thick. The total weight of electrodes is 15.5 kilos., the volume of 33 per cent. sulphuric acid 3.5 litres, and the total weight of an accumulator 35 kilos. The tension according to Siemens' torsion galvanometer is 2.05 volts., and they yield when coupled in series 40—50 cc. of electrolytic gas per minute. With these 4—8 analyses were simultaneously performed. The author gives a series of results, showing that with two fully charged accumulators 60—70 analyses may easily be performed.

Separation of Tin from Antimony.—In a former communication (this Journal, 1886, 334) the authors have given a method for this separation in presence of sodium sulphide, precipitating the antimony, adding ammonium sulphate, and then precipitating the tin. A modification, which gives better and more rapid results, is to convert the tin sulphide dissolved in sodium sulphide into the acid oxalate, and then to electrolyse the solution. This may be done in two ways, either by decomposing the sulphide with dilute sulphuric acid and oxidising the separated tin sulphide with ammoniacal

hydrogen peroxide to tin oxide, or by adding directly hydrogen peroxide until the solution is colourless, and then sulphuric acid to precipitate the stannic oxide; the separated oxide being then dissolved in oxalic acid. The authors find

that in presence of excess of oxalic acid, copper oxalate may be more rapidly electrolysed than the nitrate, and that a firmly adherent film of metal is obtained.—J. B. C.

Estimation of Nitrates in Natural Water. S. C. Hooker.
Ber. 21, 3302.

MANY years ago Graebe and Glaser discovered the fact that the addition of oxidising bodies in small quantities to a solution of carbazol in concentrated sulphuric acid produced a dark green solution. The author based a method for the estimation of minute quantities of nitrates on this reaction. He proceeds thus: A measured quantity of the water to be tested, 2 cc. or less, is mixed with 4 cc. of concentrated sulphuric acid, and after cooling a small quantity of sulphuric acid, containing some carbazol, is added. The intensity of the green colour produced is compared with that obtained under similar conditions with a known amount of potassium nitrate. The reaction is very delicate, and still applicable, if the water only contain two parts of nitric acid per million. Certain precautions must be taken in the presence of chlorides and nitrites, which will be published at some future date.—S. H.

Method for rapidly Analysing Water for Industrial Purposes, with a view to its Purification by Chemical Means.
L. Vignon. Bull. Soc. Chim. 50, 598—604.

IN most cases it is advisable to purify water, previous to using it for industrial purposes, when there is a solid residue of 0.3 grms. or more per litre of the water. The author's method consists in saturating the acid carbonates contained in the water with lime, and then precipitating all the lime and magnesia salts still in solution with sodium carbonate. Phenol-phthalein is used as an indicator, and decinormal clear lime-water is required. The titration is conducted in two narrow glass-stoppered cylinders of about 100 cc. capacity. Into one, 50 cc. of distilled water and 10 drops of an alcoholic solution of phenol-phthalein are introduced; this is then coloured by 0.2—0.5 cc. of the normal lime solution, and kept as standard. The other cylinder is filled with 50 cc. of the water under examination, 10 drops of phenol-phthalein solution, and 5 cc. of a 10 per cent. neutral calcium chloride solution. The normal lime-water is then added, until, on agitating, the solution remains coloured. The standard is now diluted until its volume corresponds to the volume of liquid in the other cylinder, and a little lime-water added to one or the other solution until the colour in both is identical. The difference in the quantity of lime-water used for the standard and for the water under examination gives the quantity of lime which has combined with the free carbonic acid in the water.

In order to determine the quantity of soda required to precipitate the lime in the water, 100 cc. of the latter are mixed in a graduated 250 cc. cylinder with the quantity of lime-water necessary to combine with any free carbonic acid, 5 cc. of phenol-phthalein solution then added, and the mixture, after shaking, allowed to settle. Exactly one-half of this solution is placed in one of the cylinders previously used for the colorimetric determination and the amount of soda solution (containing 1 gm. of Na_2CO_3 per litre) ascertained which is necessary to produce a recoloration. This must be equal in intensity to the standard made by adding to distilled water the same amount of phenol-phthalein contained in the former solution and coloured by a small quantity of the soda solution.

From the above data the quantity of lime and soda which it is necessary to add to the water may be readily deduced.

Water containing notable quantities of magnesium sulphate or chloride cannot safely be tested by this method.

—A. R.

Determination of the Metals of the Iron Group by Means of Hydrogen Peroxide. A. Carnot. Compt Rend. 107, 948—949 and 997—1000.

THE action of hydrogen peroxide on the different metals of the iron group is either that of an oxidising or reducing agent. The best known reaction is that with chromates, where dilute solutions of both when mixed yield a blue colour. This latter is very fugitive, remaining a few minutes if the solution be nearly neutral, and only a few seconds if it contain more than 1 per cent. of free H_2SO_4 or HCl . The colouration is due to the formation of a body with the

formula $\text{CrO}_3 \cdot \text{H}_2\text{O}_2$. With a sufficient quantity of H_2O_2 the chromate is finally reduced to Cr_2O_3 . On this fact the author bases a volumetric determination of chromic acid or hydrogen peroxide. The former is more readily carried out. The solution of the chromate must have a slightly acid reaction. It is titrated with a very dilute solution of H_2O_2 (the commercial product mixed with 5—20 times its volume of water); the latter being added until a drop ceases to produce a blue spot in the chromate solution. The strength of the H_2O_2 solution may be ascertained by titrating in a similar manner a solution containing a known weight of bichromate. The chromate solution should not contain more than 0.5 per cent. of chromic acid, to prevent the colouration being too dark. The dilute hydrogen peroxide solution keeps very well.

The reverse takes place when hydrogen peroxide acts on chromium salts in alkaline solution, the chromium salts being converted into chromates. A dilute solution of chromium chloride is heated to boiling, a few cc. of the H_2O_2 solution and an excess of ammonia added, and the mixture boiled again until quite yellow. Any undissolved oxide must be redissolved in acid and treated again in the same manner. The oxidation finished, the chromate may be determined again by reduction with H_2O_2 , or otherwise. This method may be used with obvious advantage for separating chromium from those metals which are precipitated by ammonia or ammonium carbonate. The process is also very useful when it is a question of separating chromates from chromium salts or, in the analysis of chrome iron ore, from alkaline aluminates.

Manganese is acted upon by H_2O_2 similarly to chromium; in acid solution reduction takes place; in alkaline solution oxidation. When a manganous salt is mixed with dilute H_2O_2 and boiled with ammonia, all the manganese is deposited as dioxide, but generally it has to be redissolved several times, &c., to free it from any other metals.

Iron salts are oxidised by H_2O_2 in acid solutions, unlike the two preceding metals. The transformation is immediate, even in the cold, and H_2O_2 is more effectual in this case than any other oxidising agent.

No analytical data are given, testifying to the accuracy of the methods described.—A. R.

Some similar Reactions of Carbazol and Pyrrol.

S. C. Hooker. Ber. 21, 3299—3301.

1. CARBAZOL, like pyrrol, gives the red colouration with a pine-wood shaving. The colourations are best produced by soaking the shaving in a hot alcoholic solution of carbazol, and then exposing it to hydrochloric acid fumes.

2. Treated with isatin and sulphuric acid (conc.), an intense blue colouration is produced. This reaction is very characteristic in the case of carbazol, and may serve as a test. An indigo-coloured precipitate, which rapidly becomes lighter coloured, is formed on adding water to the acid solution.

3. If an acetic acid solution of carbazol and benzoquinone be treated with a little sulphuric acid previously mixed with twice its volume of acetic acid, a deep carmine red solution is produced, from which water precipitates a red to red-violet substance, soluble in ether, chloroform, and alcohol. A neutral aqueous solution of pyrrol behaves similarly when treated with benzoquinone. (V. Meyer and O. Stadler. Ber. 17, 1035. This Journal, 1884, 439.) The author considers the action of benzoquinone to be that of an oxidising agent only, and similar colours precipitated by water are produced by the addition of any oxidising agents to a sulphuric acid solution of carbazol or pyrrol.

4. Picric acid combines with pyrrol to form an unstable compound, which melts at about 71° . The compound of carbazol and picric acid is a characteristic and stable body melting at 186° .—C. A. K.

Volumetric Estimation of Acetone in Methyl Alcohol.

J. Messinger. Ber. 21, 3366—3372.

METHYL alcohol which is employed in the manufacture of aniline dyes should contain only a very small quantity of

acetone, and it is therefore important to have some quick and accurate method by which the quantity of acetone can be ascertained.

When acetone is treated with iodine and potash the following reactions take place :—

If a known quantity of iodine be added to an alkaline solution of the methyl alcohol, for every two molecules of acetone present six molecules of iodine (I_2) will enter into combination and form iodoform. If the solution be then acidified the excess of iodine present as potassium iodide and iodate, will be liberated and can be estimated by titrating with sodium thiosulphate.

The analysis is carried out as follows:—20 cc. or, if the sample contains a considerable quantity of acetone, 30 cc. of potash, and 1–2 cc. of the methyl alcohol are shaken together in a stoppered 250 cc. flask, and a known quantity (20–30 cc.) of a $\frac{1}{2}$ -normal iodine solution added. The mixture is shaken until it becomes clear, just acidified with hydrochloric acid, and excess of decinormal sodium thiosulphate solution run in. Starch is then added and the excess of sodium thio-sulphate titrated with the $\frac{1}{2}$ -normal iodine solution.

The potash solution employed is made by dissolving 56 grms. of KOH in one litre of water; the hydrochloric acid is of sp. gr. 1.025, and the volume added should be the same as that of the potash.

If r be the volume (in cc.) of the iodine solution required to combine with the acetone, and u the volume (in cc.) of the methyl alcohol taken, then the quantity of acetone, by weight, in 100 cc. of the sample is equal to

$$r \times 0.1933448$$

"

A large number of test analyses are given showing the results obtained with prepared solutions of chemically pure methyl alcohol containing from 0.2 to 2 per cent. of acetone and also with aqueous solutions of acetone and samples of commercial methyl alcohol. The results in all cases are very satisfactory.—F. S. K.

Kjeldahl's Method for the Determination of Nitrogen.

G. Lunge. Zeits. f. angew. Chem. 1888, 661–662.

The method proposed by Meldola and Moritz (this Journal 1888, 63–64) for purifying sulphuric acid intended for use in the determination of nitrogen by Kjeldahl's method, is adversely criticised. In the paper referred to, it is assumed that the nitrogenous impurities exist in the form of ammonium sulphate. But it is not always so. It is well known that the most usual impurity in purified sulphuric acid is nitrosylsulphonic acid, and ammonium sulphate is added to prevent injury occurring to the platinum stills during the concentration of such acid. Ammonium sulphate is present in the rectified acid only when a larger quantity has been added than is required in the equation—

But frequently the rectified acid contains nitrous acid. Again, the assumption of Meldola and Moritz that the excess of nitrous acid is driven off by heating, is incorrect. When a nitrite is added to sulphuric acid, nitrosylsulphuric acid is formed, and Lunge has shown (Dingl. Polyt. J. **233**, 155 and 237; Ber. **12**, 1058) that this is a very stable compound. Even after prolonged boiling of a solution of this body in concentrated sulphuric acid, no decomposition takes place, but usually a small quantity of it distils over with the sulphuric acid. This fact has been again verified by a series of experiments, of which the following is an example. Nitrite of soda was dissolved in pure sulphuric acid; a portion tested with permanganate gave the proportion of 0.1928 gm. of HNO_3 in 200 cc. 200 cc. were then taken and boiled for four hours; 80 cc. distilled over. The nitrous acid was estimated and the total quantity added found again :—

	Grm.	HNO_3
In the residue	0.1842	
In the distillate.....	0.0096	"
	0.1938	"

Meldola and Moritz's method of purification can, therefore, only be applied when the quantity of ammonia present has been determined, and the nitrite must not be added in excess, and, in such a case, a correction is more easily made, and the purification entirely dispensed with.—E. B.

On the Estimation of Nitrogen and Phosphoric Acid in Organic Bodies. O. Lunge. Chem. Zeit. **12**, 1587–1588.

In the following method Lunge has made the attempt to employ the solution prepared according to Kjeldahl's method for the estimation of nitrogen, and phosphoric acid as well. He thus aims at simplifying the analysis of such bodies as bone ash. 10 grms. of the substance are transferred to a flask (300–350 cc. capacity), 50 cc. of concentrated sulphuric acid, and 0.5–1 gm. of copper sulphate added. At first the mixture must be heated very carefully, and it should only be raised gradually to the boiling-point, when carbonisation is complete. After two hours' (in exceptional cases, 2½–3 hours) vigorous ebullition, the reaction should be complete, and after the precipitate has subsided, the supernatant liquid should be of a pure, light green tint. When cold the whole is rinsed into a 500 cc. flask, which has been previously half-filled with water. The mixture is then cooled and made up to half a litre.

During ebullition, the flask should occasionally be shaken about in order to wash down the small carbonised particles which adhere to the sides. The dilute solution is filtered and 50 cc. of the filtrate (corresponding to one gm. of the original substance) taken for the phosphoric acid estimation. For this purpose 100 cc. of "Märker's citrate solution" and 25 cc. of magnesia mixture are added, and the whole stirred up till precipitation sets in. The precipitate can be filtered off after a quarter of an hour. "Märker's citrate solution" is prepared as follows: 1,500 grms. of citric acid are dissolved in 3 litres of water and 5 litres of 24 per cent. ammonia, and 7 litres of water added. For the nitrogen estimation, 50 cc. of the filtrate are diluted with water, an excess of soda-lye and a few small pieces of zinc added and the ammonia distilled off. The results obtained by this method are excellent. Very good results were also obtained when 0.5 gm. of mercury was used instead of the copper sulphate; and the destruction of the organic matter took place much more rapidly, being completed in 1 to 1½ hours. The author, however, prefers not to employ mercury, as mercury amido-compounds might be precipitated with the phosphoric acid, and though these compounds would no doubt volatilise when the precipitate is ignited, the escape of the poisonous mercury fumes might have unpleasant consequences. The precipitates obtained both by the mercury and the copper method were perfectly white.—F. W. T. K.

The Testing of Fats. Meeting of the Austrian Society for the Advancement of Chemical Industry. Chem. Zeit. **12**, 1641.

In discussing tests for fats L. Ausserwinhler lays special stress on the determination of the saponification-, acetyl-, and iodine values as means for distinguishing and recognising fats.

E. Lauber has found the physical properties of pure olive oil to vary according to the nature of the ground on which the olives have been grown, the time of their harvest, the method of pressing them, the storing of the oil and the action of light on it. The results obtained with pure olive oils by the elaidin test vary according to the above circumstances.

Nettl agrees with Lauber; F. Storck, on the other hand, holds that with sufficient experience of the physical properties of pure olive oils and of their behaviour when

subjected to the claudin test, the nitric and sulphuric acid tests, and the silver test, these are sufficient to determine the purity of a sample.

W. Gintl points out that olive oil which has been exposed to direct sunlight for about 14 days no longer gives the claudin reaction. Italian olive oil is denaturalised on the frontier with rosemary oil. Colour tests are therefore unsuitable for such oil. Gintl and L. Storek are in favour of the more modern quantitative methods, as these allow of a more objective judgment and are less liable to error.

—F. W. T. K.

Estimation of the Starch in various kinds of Grain, and Valuation of these for the Manufacture of Starch, &c.
H. Schreib. Zeits. f. angew. Chem. 1888, 694—696.

(See under XVI., page 127.)

New Books.

THE FUNDAMENTAL PRINCIPLES OF CHEMISTRY. Practically taught by a New Method. By ROBERT GALLOWAY, M.R.I.A., F.C.S. London: Longmans, Green, & Co. New York: 15, East 16th Street. 1888.

THE author in his Preface finds fault with the ordinary chemical text-books that are in use in schools, and for teaching junior students generally. "Many of these books," says he, "are little more than mere compilations of unclassified facts; hence the reason is not cultivated, and consequently the science is not attained, for unless the first is reached the second is not gained." The text, covering 346 pages and embellished with 71 wood engravings, is divided into chapters, in which the matter is treated progressively, according to the following steps. Chap. I. Matter.—The Physical Properties of Bodies. II. Molecular Attraction.—Heat and Temperature. III. Gravitation.—The Physical Properties of Gases. IV. Ebullition.—Elastic Force of Vapours. V. Density. Specific Gravity. VI. Sublimation.—Solution.—Precipitation. VII. Adhesion.—Capillary Action. VIII. Elements and Compounds.—Chemical Affinity. IX. The Different Classes of Compound Substances. X. General Laws of Chemical Combination. XI. Nomenclature and Notation.—Basic Substances. XII. Acids and Acid Anhydrides. XIII. Salts.—Their Formation and Properties. XIV. The Mode of Expressing Chemical Changes. XV. Combination of Similar Atoms.—Determination of Atomic Weights. A set of exercises with answers is also given. The book is of 8vo. size, bound in cloth.

WATER ANALYSIS. A Practical Treatise on the Examination of Potable Water. By J. ALFRED WANKLYN, M.R.C.S. London: Trubner & Co., Ludgate Hill. Seventh edition. 1889.

As the Preface states, the seventh and present edition of this book contains a large part of the last edition, which reappears without alteration; but the beginning of Part II. is altered by there being two new chapters added, viz., a chapter on Specific Gravity (taking the place of an old chapter on the same subject), and an additional chapter on Carbonic Acid. It is also announced that for the first time, "a real connexion between the specific gravity and the contents of a drinking-water has been experimentally demonstrated." Part III. has been enlarged, and includes a section on the classification of natural waters. There is a section also dealing with the solution of lead by certain kinds of drinking water. The bulk of the book is slightly increased, as may be judged from the foregoing. It is bound in black cloth, is of 8vo. size, and the price is 5s.

Trade Report.

(From the Board of Trade Journal and other sources.)

TARIFF CHANGES AND CUSTOMS REGULATIONS.

RUSSIA.—FINLAND.

Tariff Changes.

Note.—Kilogramme = 2·204 lbs. 100 penni = 9½d.

The duty on Chilean saltpetre has been reduced from 90 penni to 20 penni per 100 kilograms.

JAPAN.

Abolition of Export Duties on certain Articles.

An Imperial ordinance has been promulgated abolishing, from the 1st January 1889, the export duty on drugs and certain other articles, and stating that in the event of a re-imposition of the duty, a notice of six months will be given. The following is a list of the articles, as contained in the translation in question:—

Drugs (camphor excepted), prepared medicines, dye-stuffs, colours, glue, isinglass, candles, Japanese ink and similar articles, ink pads, washing-powder, soap, tooth-powder, and blacking, medical and scientific instruments, perfumery, articles for the toilet, asbestos, deposits of thermal springs, cement, flowers and gum of plants and trees, powdered railnuts, spirits, vinegar, oils, and prepared spices.

NEW CUSTOMS TARIFF OF QUEENSLAND.

The following is a statement of the rates of Customs duty now levied under the new tariff, assented to on the 25th October last:—

Classification of Articles.	Rates of Duty now levied.
	£ s. d.
Gunpowder.....	Reputed lb. 0 0 1
Tallow, stearine, and lard	" 0 0 1½
Blue, candles, and glue	" 0 0 2
Mustard, spices, and acetic acid.....	Lb. 0 0 3
Leather (except otherwise enumerated)	" 0 0 4
Bicarbonate of soda and resin.....	Cwt. 0 1 0
Caustic soda	" 0 1 6
Soda crystals	" 0 2 0
Acid, sulphuric	Cwt. 0 2 6
Paints (wet and dry) and lead (white and red) ..	" 0 3 6
Saltpetre	" 0 4 0
Soap.....	" 0 10 0
Cement.....	Barrel 0 2 0
Vegetable oils (in bulk).....	Gallon 0 1 0
Mineral oils and turpentine.....	" 0 0 6
Opium	Lb. 1 0 0
Sugar (refined)	Cwt. 0 6 8
Glucose	" 0 10 0
Perfumed spirits	Liq. gall. 1 0 0
Methylated "	" 0 5 0
Sulphur, nitrate of soda.....	5% ad val.
All other goods	15% ad val.

The following articles are exempt from duty:—

Dye; all explosives, save gunpowder; manure; muntz metal; paper; quicksilver; safety matches; salt; and soda ash.

SWITZERLAND.

Classification of Articles in Customs Tariff.

"Hydroleine" (soda, calcined, mixed with a little soap).—Category 18. Duty, 2 francs per quintal.
 "Poliment" (mixture of alumina, soluble glass, and ground graphite).—Category 30. Duty, 60 cents per quintal.
 "Antipyrine."—Category 60. Duty, 7 francs per quintal.

UNITED STATES.

Customs Decisions.

So-called "hashish," which is not the crude drug known to commerce by that name, but is a preparation of Indian hemp, used medicinally, is dutiable at the rate of 25 per cent. *ad valorem*, under T. I., 93; and so-called "Butyr-cacao," an expressed oil, is dutiable at the same rate, under T. I., 92.

Asbestos, manufactured or unmanufactured, cannot be classified under the provision in the free list, T. I., 754, for "paper stock," inasmuch as the substance is otherwise specially provided for, as follows: when manufactured, under Schedule A. (T. I., 39), and when unmanufactured, under the free list, T. I., 538.

A substance, consisting of a mixture of caustic soda and lime, is held to be dutiable at the rate of 25 per cent. *ad valorem*, under the provision in Schedule A. (T. I., 92), for chemical salts not provided for by name; and certain powdered copper, which is not the "regulus" or black or coarse copper of commerce, but consists of metallic copper reduced, probably by chemical agencies, is held to be dutiable at the rate of 45 per cent. *ad valorem*, under the provision in Schedule C. (T. I., 216), for manufactures of copper.

SOUTH AMERICAN ANIMI RESIN.

It is announced that the Government of the Republic of Colombia, in order to stimulate the production and importation of animi resin from that country, has decided to grant an export bounty of 8 per cent. *ad valorem* on all shipments of the resin. The trade is at present concentrated in the hands of a native firm in the department of Bolivar, where it is found in large quantities deposited in the earth as a product of the *Hydnocarpus Courbaril* and other trees. —*Chemist and Druggist*.

MISCELLANEOUS TRADE NOTICES.

PHOSPHATE OF LIME IN RUSSIA.

The *Engrais* states that there exist in Russia important beds of phosphate of lime, occupying almost the whole area of an immense triangle, the base of which would pass from Odessa to Orenburg. The number of strata, one above the other, varies from three to seven, but for the most part the deposit is a mere vein. The beds are at one place near the surface, in another they are several hundred metres below the ground. The phosphate often takes the form of nodules of very diverse size and colour, but it is also found in slabs, or even in massive blocks. The principal bed in Russia, that of Koursk, forms an immense basin, extending for a length of more than 150 kilometres.

MANUFACTURE OF GLASS IN ITALY.

The *Volks-wirtschaftliche Wochenschrift* for the 3rd January last announces that a company has been formed to establish a manufactory of window and table glass at Milan. The German newspaper adds that the importance of this fact will not escape the notice of exporters in other countries. Hitherto, Italy has almost entirely depended upon foreigners for glasswares, but it is intended to start the new company on such a scale as, if possible, to exclude foreign glass altogether from the Italian market. The technical management of the factory is to be placed in the hands of a Belgian expert. It appears that a capital of a million francs has already been subscribed. An Italian firm in Mannheim is interested in the enterprise.

LOCALITIES IN WHICH MANGANESE OCCURS IN THE UNITED STATES.

While there has been a constant and persistent search for new deposits of manganese during the past year, no new development of any importance has been reported outside of the localities that have been described in the previous volumes of "Mineral Resources." Indeed, some localities regarded as quite promising at the time the report for 1886 was made up have proved to be of little value, and the chief production is still confined to the localities that have been noted as manganese producers for many years. The extensions of the iron-ore regions in the Lake Superior district, in which it was hoped deposits of manganese ores might be found, have so far produced only insignificant quantities of an ore with more than 44 per cent. of metallic manganese, the chief product being a manganoferous iron ore containing from 4 to 10 per cent. There are somewhat encouraging prospects of the discovery of manganese

ore in North Carolina and also in Western Arkansas. Yet it is still true that Crimora (Virginia), Cartersville (Georgia), and Batesville (Arkansas), furnish practically all the manganese ores mined in the United States. —*J. D. Weeks*.

THE MANUFACTURE OF SPIEGELEISEN.

During the past few months the North Chicago Rolling-mill Company have been making spiegeleisen at one of their furnaces. They have been turning out about 600 tons a week. The ores used come from Batesville, Ark., and it is thought that the company will soon be able to obtain it in sufficient quantities to supply them with all the spiegeleisen they will require at their entire works. Heretofore, this metal has been imported from England and Germany, and the company have bought annually as much as 20,000 or 25,000 tons. That which has just been made at the North Chicago furnace is what is known as 50 per cent. manganese metal. A small quantity of spiegeleisen has been made heretofore in some of the Western furnaces, but it was of an experimental character. This is believed to be the first case where this metal has been manufactured in paying quantities in the Western States.

—*The Ironmonger*.

THE SMYRNA CHEMICAL INDUSTRY.

A correspondent calls attention in a foreign contemporary to the possibility of working up an export trade from Asia Minor in the many medicinal drugs which are indigenous in the country, but are at present exported to a comparatively small extent only. Herbs suitable for liquor-manufacture are especially abundant in the country. One of the liquorice-juice works in Asia Minor, owned by a Swiss, and said to have been very well appointed, has ceased working. —*Chemist and Druggist*.

BOGUS REPRESENTATIVES IN ROMANIA.

The existence throughout Roumania, but especially in Bucharest, of an exceptionally numerous fraternity of long firms and bogus agents has hitherto rendered business with that Danube State extremely risky. Some improvement is likely to be effected in this respect by a law which compels all agents of foreign manufacturers and traders to deposit with the Bucharest Chamber of Commerce a declaration by their principals, legalised before a Roumanian notary public, to the effect that the agent named therein is the sole representative of his principals for the whole or part of the country, that he has the right to act in all commercial matters on their behalf, to represent them in courts of justice, and to collect accounts in their name. After the deposition of this deed with the Chamber of Commerce, the agent receives from that body a licence permitting him to act as the representative of his principals. The law came into operation on January 1. —*Chemist and Druggist*.

THE DECIMAL ASSOCIATION.

An association has been formed under this title for the purpose of promoting the adoption in this country of a decimal system for currency and for weights and measures. The association does not take upon itself to recommend the adoption of any particular unit of currency, but it will press for the adoption by the Government of a decimal system of coinage. It is thought that the Government is favourably disposed to the object of the association, which is well supported by members of both Houses of Parliament and other influential persons. The association's offices are at Botolph House, Eastcheap, E.C., and members' subscriptions range from 10s. per annum upwards. During the last session a memorial signed by one hundred and fourteen members of the House of Commons, most of them connected with manufacturing and trading interests, was presented to the Chancellor of the Exchequer to urge upon him the importance of the adoption of a decimal system of coinage and weights and measures. —*Chemist and Druggist*.

REPORT ON MANURE MANUFACTURE. DR. W. COHN.

Chem. Indust. Oct. 1888, 429—431.

The introduction of powdered Thomas-slag has had a considerable effect on all manfactories which produced phosphatic manures, and many of them have now erected plant for grinding the slag. If the demand for the above article continues as active as it has been, and of this there appears to be a good prospect, the extra outlay in plant will not be misplaced. Crude slag and considerable quantities of powdered slag are imported from England, but these usually contain a smaller percentage of phosphorus pentoxide than the slags obtained in Germany. Cohn offers no opinion as to whether the Thomas-slag exported from England represents a surplus left after all possible demand for home supply has been satisfied, or whether the conservative feeling in England hinders the employment of Thomas-slag in favour of super-phosphates and bone-flour. He points out, however, that the moist climate of Britain should be very favourable towards the employment of Thomas-slag, if the latter really possesses all the advantages which several German experimental stations claim for it. For the purpose of grinding the slag, specially constructed ball-mills have come into use during the last few years which are said to be a great improvement.

Bone-flour is now being imported into Germany not only from Austria, France, Russia, and America, but also from India; and Russian shipments are now coming in fairly large quantity from Odessa as well as from the Baltic ports.

Amongst artificial manures may be included preparations which by being added to stable manure preserve its constituents from dissipation, and themselves supply valuable manurial constituents.

Finely-powdered manure gypsum has long been used for this purpose, and during the last few years potash salts have also been used, although the latter are liable to produce inflammation of the hoofs of the cattle if they are not carefully strewn about the stable.

Calcium sulphite has been introduced for the same purpose, but is no better than gypsum, and may be worse on account of retarding the oxidation of the manure.

Superphosphate of lime is another substance which has been employed for the preservation of manures. It is the mud retained in the filter-presses of certain phosphate factories which work with phosphates of lime containing only a small percentage of phosphoric acid. It consists of gypsum and acid calcium phosphate. This substance appears to be a good one for the purpose. No doubt a mixture of gypsum and superphosphate would do as well. In the latter case the farmer would have greater ease in regulating the quantity of phosphoric acid he wishes to have in his manure. Eventually his choice will probably be regulated by the ease with which he can obtain the superphosphate gypsum or the separate constituents.

The mixture of superphosphate and Chili saltpetre, which is principally used in spring, has been objected to on the ground that the latter is easily decomposed when thus mixed, and that loss of nitrogen is thus entailed. Experiment has, however, shown that this is only the case when badly prepared superphosphate is used containing much free sulphuric acid.

The employment of the new manure, potassium phosphate (30 per cent. of potash, 40 per cent. of phosphoric acid), is said to have yielded very good results. The unsatisfactory results often obtained with potash salts is due, according to Adolf Mayer, to the high percentage of chlorides and sulphates in them. Still the consumption of potash salts has increased, for though the employment of the potash manures manufactured in the Stassfurt factories has decreased, the use of kainite and carnallite has increased considerably. These latter salts are principally used, mixed with Thomas-phosphate powder. It is more especially the use of carnallite which has increased, for although this contains only three-quarters of the quantity of potash present in kainite, it is half as cheap again.

The production and consumption, too, of ammonium sulphate is increasing. The experiments ordered by the Minister of Rural Economy are not yet complete, but so far as they have gone they show that in the case of ammonium sulphate more than in that of any other manuring agent, the action depends on the physical and chemical nature of the soil.

Manuring substances have as a rule become cheaper, and their consumption has increased. The benefits to be derived by their use seem to be becoming more and more recognised.—F. W. T. K.

SULPHUR PRODUCTION IN SARDINIA.

Chem. Zeit. 12, 1659.

The yield of the sulphur mines in Northern Italy was only 21,663 tons in 1887, as against 23,274 tons in 1886.

The decrease is partly due to the diminished yield of the Boratella pits, which have been partly worked out, and to the collapse of the Cesena Sulphur Company, Limited, which has pretty well exhausted the basin of the Romagna. The company has spent large sums in the search for new places of production, and in the attempt to work further those commenced by its predecessors, but without avail; and after a few years the company saw itself confined to the pits at Boratella. The production of the company of the Romagna shows a slight increase. The Monteverchie shaft, which belongs to this company, is not yet complete.

Permanent progress is noticeable in the provinces of Pesaro and Urbino. The new shaft in the mine of San Lorenzo in Zolinelli, has increased the daily yield of the latter to 200 tons of ore. The loss of work in the Boratella mines has caused many of the workmen to turn again to the old Casalbano mines, which they work in small gangs. The yield has so far only been moderate.

The treatment of the crude sulphur has undergone little modification. A new refinery with three ovens and 34 refining kilns has been erected at Porto Corsini, near Ravenna. It turns out 6,000 tons a year. In 1887 the various refineries have produced 24,000 tons of ground sulphur, an increase of 3,516 tons over last year. The exact quantity of finely-ground sulphur produced is not known, but it probably represents $\frac{1}{3}$ of the total refined sulphur. The Albani Pit Company produces special preparations, and to meet the increased demand, especially for their acid sulphur, has induced them to enlarge their new mill at Fano. During the last wine season the Pesaro manufactory turned out 9,500 tons of acid sulphur containing 0.22 per cent. of sulphuric acid, and 1,105 tons sulphur containing between 1 and 8 per cent. of copper sulphate.

The presence of the above quantity of sulphuric acid has been found the most suitable in the treatment of the vine disease. This acid is not added, as is done in some parts of Italy, but is a natural adjunct of the preparation. Artificial acidification does not yet appear to have been introduced in the factories.

Though almost the whole production was disposed of during the wine season, prices have been kept low by Sicilian competition.

The average price per centner for the year has been:—

	Fr.
Crude sulphur.....	8.75
Refined in loaves.....	10.40
Sulphur in sticks.....	13.00
Coarsely powdered.....	13.10
Sublimed.....	14.50
Acidified powdered.....	17.65
Powdered and containing copper...	21.50
Flowers of sulphur, washed.....	35.00

The following are the statistics for 1887:—

Province.	Number of Pits in Work.	Quantity of Crude Sulphur.	Total Value.	Number of Workmen.		
				Grown up.	Under 15 Years.	Total.
Anicene.....	1	Tons, 34	Fr. 2,680	96	..	96
Porti.....	10	13,026	1,095,006	1,231	7	1,238
Pesaro and Urbino.....	5	8,603	668,269	1,304	48	1,352
Totals.....	16	21,663	1,765,955	2,631	55	2,686

—F. W. T. K.

THE SALT DEPOSITS OF NEW-YORK.

In our issue of November 10th, 1888, we mentioned that the persevering efforts of Mr. W. B. Cogswell, of the Solvay Process Company, had resulted in the discovery of a bed of rock-salt about 17 miles south of Syracuse, and that other wells were being sunk to reach the salt at other points where it comes nearer the surface of the ground. We now have an interesting report by Dr. T. E. Englehardt on behalf of the State, detailing the results obtained by the sinking of 63 deep wells in the central and western counties of the State. Few of these were sunk with the expectation or the object of finding salt, most of the work being done in prospecting for oil or gas, but in only seven of them was there a failure to meet with rock-salt or brine.

In the case of the Solvay Company's well, the bed of salt was reached by the drill after passing through 40 feet of Marcellus shale, at a depth of 678 feet, 150 feet of carboniferous limestone, 50 feet of "water lime," and 300 feet of Helderberg rock, making a total depth of 1,218 feet, and here it has a thickness of 47 feet.

This was considered satisfactory and at a workable depth, but the thickness of this bed, we learn from Dr. Englehardt's report, was far below that previously discovered some two or three years ago in sinking for gas at Ithaca, about a mile from the grounds of Cornell University, where the drill encountered the first layer of salt at a depth of 2,244 feet, and in the succeeding 470 feet the aggregate of salt layers amounted to 248 feet, the thickest being 54 feet, and being only separated by a layer of shale, 6 feet thick, from one of salt above of 24 feet, and by another layer of shale below, 12 feet thick, from 17 feet of salt, making a total thickness of 95 feet of salt in one part of the stratum, with 18 feet of shale interposed.

The great depth at which the salt is met with in most instances deprives it of the value it would otherwise have, the least distance from the surface being 710 feet; but it is expected that this, and even the 1,200-foot well of the Solvay Company, can be profitably utilised in the same manner, and under conditions similar to the rock-salt beds in the Durham salt district in England, where, by pumping fresh water into the wells, a strong brine is procured which can be evaporated on the spot, or piped, as would be the case in this instance, to the Solvay Works, near Syracuse.

All but 10 of the wells mentioned in the report have been sunk to below the level of the sea, the depths below sea level being from 259 to 1,818 feet.

The exact return from the 63 wells reported upon is as follows: Brine was met with in 14, two of which are useless for salt-making in consequence of the bitterness imparted by other mineral salts; rock-salt met with in 42, varying in thickness from $3\frac{1}{2}$ to 248 feet, and as we have already mentioned, neither salt nor brine in seven cases, although in some of these last cases the sinking was persevered with as far as 2,000 feet. The average thickness of salt may be taken to range between 40 and 80 feet, and with the exception of the one instance in which there is only $3\frac{1}{2}$ feet, there is none with less than 12 feet.—*Engineering and Mining Journal*.

A VALUABLE BLUE REDISCOVERED.

Professor Fouqué, of the College de France, at the last meeting of the Academy of Sciences (February 18) read an important memoir on the blue pigment used by the ancient Romans for wall decorations. It is a magnificent colour, as bright to-day as when first applied, and is found in the fresco paintings of Pompeii and other monuments dating from the Roman period. Its production is one of the lost arts, as there is no record of the pigment being used after the invasion of the Barbarians. Modern chemists have more than once tried to ascertain the nature of the compound, but beyond the point that it contains copper nothing definite was discovered. M. Fouqué thinks the lack of success is owing to the fact that the ancients followed no exact rules or proportions. Having secured comparatively copious specimens of the coreuleum—such is the old name of the pigment—he has succeeded not only in analysing it, but also in finding a process for making it regularly in quantities. The compound is, according to M. Fouqué, a quadruple silicate of copper and lime, which may be prepared with silica, oxide of copper, and lime, with or without any fluxes. The ancients simply made it with sand, calcined or roasted copper, and lime, but kept to no regular proportions. He worked differently, and managed to obtain an exact chemical combination, which is neither

a glass nor an enamel, but a crystalline substance of the composition already mentioned. The crystals are perfectly definite, and strongly dichroic appearing deep sky-blue when viewed from the surface, and pale rose edgewise. The only difficulty in the preparation is the heating. A bright red heat is necessary to effect the combination, but on heating too much the blue colour is lost and an aventurine green glass is obtained, a circumstance which must have rendered the process a delicate one in old times. Nowadays, however, with the means at our disposal, the difficulty is trifling, and kilns, of the corallum could easily be made in the College de France laboratory. It is a very stable pigment, so far as chemicals are concerned, as it stands, unaffected, boiling with sulphuric acid or potash lye, as well as quicklime and hydrogen sulphide. That it will be air and water proof is abundantly shown by the old fresco paintings. M. Fouque considers, therefore, it would be a great boon to the arts to produce the blue commercially, and promised his assistance to any French manufacturer who will undertake the fabrication. While examining the fine specimens of the rediscovered blue presented by M. Fouque, M. Berthelot, who is well versed in ancient chemical lore, remarked the corallum in question was no doubt the Alexandria blue, known in Egypt about the beginning of the Christian era, and taken to Pozzuoli, whence its use spread all through Italy. He agreed with M. Fouque that the pigment was unknown to the Assyrians and ancient Egyptians, and is no doubt a most valuable one.—*Chemist and Druggist*, 25th February 1889.

OFFICIAL REPORTS.

THE WORKING OF THE MERCHANDISE MARKS ACT.

See Board of Trade Journal for February, p. 204.

THE PHOSPHATE MINING INDUSTRY OF SOUTH CAROLINA.

The annual report of the Agricultural Department gives some interesting figures with regard to the phosphate mining in South Carolina, which in its way is nearly as curious as the amber mining, or rather fishing, in the Baltic, as a large proportion of the phosphate rock is obtained by dredging in the rivers of the State. The river companies, as they are called, and private firms which secure their product by dredging, pay a royalty of 1 dol. a ton to the State for the privilege of extracting phosphate rock below water, and in this way the State receives a considerable revenue, the amount paid in the year ending August 31st, 1888, being 186,993 dols.

This rock, recovered from the beds of the rivers and marshes, is the hardest and best quality of phosphate, and fetches the highest price in the market, and up to the present time has been almost exclusively shipped and sold in Europe. In the past year, out of a total production of 190,274 gross tons, only 29,381 tons were used in the United States, the balance being shipped abroad. The higher freights ruling since the middle of the past year has had an unfavourable influence upon this branch of the industry, the production showing a falling off of more than 20,000 tons, and the shipments in June, July, August, and September of 1888 being only 40,326 tons, against 83,106 in the corresponding period in 1887.

This drawback to the industry cannot, apparently, be remedied by any great economies in the production, and the price cannot be advanced in Europe with any benefit, as, with a slight improvement in that direction, Belgian, Spanish, and other phosphates come into competition with the American supply and shut out the demand, so that the only relief to be looked for is a reduction of freights. The preference of the American manufacturers of fertilisers for the land rock does not seem to be based so much on the price as the hardness of the river rock, which they claim costs 75 cents to 1 dol. more in grinding. During the year 1888 the production of land rock was 259,330 long tons, of which only 3,650 tons were shipped abroad, while 60,000 tons were used in South Carolina, and the balance of 195,680 tons was manufactured in other parts of the country.

The land miners work in combination as to prices and periods of contracts, with very few and insignificant exceptions, and in this way are enabled to maintain a profitable return for their labour; but we are under the impression that, if the objection of the American manufacturers to the hard rock could be overcome, some of the more important of the river companies, which are most favourably situated for production, would be ready to sell phosphate at prices below that of the land rock combination. From the Geological Survey report we learn that the production for the year 1887 was 480,558 long tons, showing an increase of over 50,000 over the previous year, but from the more recent figures that we have given for the year 1888 the production of the past year is not likely to exceed that of 1886. The report of the Geological Survey criticises the method of using phosphate rock, and points out that, owing to the expensive treatment it receives, although a ton of Carolina phosphate costs only 6 dols., the price of the manufactured product is about 30 dols. a ton at the factory. That much of this costly treatment might be saved, and the fertiliser sold at a much lower price, is probable, and we hope will be brought about.—*Engineering and Mining Journal*.

STATISTICS.

LEADING IMPORTS IN JANUARY.

Amongst the principal imports during January were the following, which are compared with those during the same month of 1888, and also with those of December 1888:—

Article.		Month of January 1889.	Month of January 1888.	Month of December 1888.

THE TRADE OF PERSIAN GULF PORTS.

The following articles pertaining to the drug trade were imported into and exported from the two Persian Gulf ports, Bushire and Banderabass, in 1887:—

	Bushire.	Banderabass.
IMPORTS.	Dollars.	Dollars.
Drugs and medicines	37,000	4,445
Dyeing materials	2,200	..
Glass and glassware	37,000	..
Indigo	200,000	111,060
Spices	55,504	37,000
EXPORTS.		
Drugs	14,815	22,000
Dyeing materials	22,000	111,060
Gums	22,000	15,000
Opium	1,777,000	880,000
Seeds (cumin, &c.)	20,000	18,000
Rose water	44,500	..

—*Chemist and Druggist*.

PROGRESS OF THE BASIC OR THOMAS-GILCHRIST PROCESS DURING THE TWELVE MONTHS ENDING 31ST DECEMBER 1888.

The total make of steel and ingot iron from phosphoric pig during this period amounts to 1,953,234 tons, being an increase over the make for the previous 12 months of about 218,753 tons, and making the total production of basic steel to this date 8,570,000 tons.

It will be noticed that of the above-mentioned make of 1,953,234 tons, no fewer than 1,495,032 tons were ingot iron containing under 0.17 per cent. of carbon.

The makes of the various countries for the 12 months ending 31st October 1887, and 31st December 1888, respectively, are as follows:—

	1887.		1888.	
	Total.	With under 0.17 Per Cent. Carbon.	Total.	With under 0.17 Per Cent. Carbon.
England.....	Tons. 364,526	233,358	Tons. 493,594	276,476
Germany, Luxemburg, and Austria.....	1,102,496	826,609	1,276,070	1,026,033
France.....	176,500	123,049	222,533	158,223
Belgium and other countries.....	60,959	39,716	46,237	32,300
Totals.....	1,704,481	1,222,732	1,953,234	1,495,032

With this 1,953,234 tons of basic steel were produced some 600,000 tons of slag (containing about 36 per cent. of phosphate of lime), most of which was used as a fertiliser.

RAILWAY AND CANAL TRAFFIC ACT, 1888.

THE NEW RAILWAY CLASSIFICATION AND REVISED RATES AND CHARGES.

(From the "Ironmonger," Feb. 16th, 1889.)

On Saturday, February 9th, being the last day under the Railway and Canal Traffic Act, 1888, the whole of the railway companies deposited with the Board of Trade their proposed new classification, together with their revised schedules of rates and charges. For the sake of comparison and general convenience we have dealt with the chief companies in the following manner, which will enable those who are interested to gather the information they require in a ready and certain manner.

PROPOSED MAXIMUM RATES AND CHARGES.
PART I.—GOODS AND MINERALS IN RESPECT OF MERCHANDISE IN CLASS A.

Name of Railway Company.	Proposed Maximum Rates for Conveyance.				Proposed Station Terminal at each End.		Proposed Service Terminal at each End.	
	For the first 10 Miles or any part of such Distance.	For the next 20 Miles or any part of such Distance.	For the next 20 Miles or any part of such Distance.	For the remainder of the Distance.	At large Towns, as defined.	At any other Station.	At large Towns, as defined.	At any other Station.
	Per Ton per Mile. <i>s. d.</i>	Per Ton per Mile. <i>s. d.</i>	Per Ton per Mile. <i>s. d.</i>	Per Ton per Mile. <i>s. d.</i>	Per Ton. <i>s. d.</i>	Per Ton. <i>s. d.</i>	Per Ton. <i>s. d.</i>	Per Ton. <i>s. d.</i>
London and North-Western (<i>see special Table</i>)
Great Western	1½	1½	0½	0½	0 8	..	0 6	..
Great Northern	1½	1½	0½	0½	0 8	0 6
London and South-Western	2	1½	..	1	0 8	0 6
London, Brighton, and South Coast	2	1½	..	1	0 8	0 6
South-Eastern	2	1½	..	1	0 8	0 6
Furness Railway	2½	1½	0½	0½	..	0 6
Lancashire and Yorkshire (<i>see special Table</i>)
Manchester, Sheffield, and Lincolnshire	1½	1½	0½	0½	0 8	0 6
North British	2½	1½	1	0½	0 8	0 6
North-Eastern	2	1	..	0½	0 6	0 6
Midland	1½	1½	½	½	0 8	0 6
c Glasgow and South-Western	2½	1½	1	0½	0 8	0 6
Great Eastern	1½	1	0½	0½	0 8	0 6
London, Chatham, and Dover	2	1½	..	1	0 8	0 6
d Caledonian	2½	1½	1	0½	0 8	0 6

c and *d*. The second column is for the "next 10 miles," &c.
These are special rates over portions of the above lines for which the original paper must be consulted.

GOODS AND MINERALS IN CLASS B.

Name of Railway Company.	Proposed Maximum Rates for Conveyance.				Proposed Station Terminal at each End.		Proposed Service Terminal at each End.	
	For the first 10 Miles or any part of such Distance.	For the next 20 Miles or any part of such Distance.	For the next 20 Miles or any part of such Distance.	For the remainder of the Distance.	At large Towns, as defined.	At any other Station.	At large Towns, as defined.	At any other Station.

* and b. The first column is for the "first 20 miles," &c.

c and d. The second column is for the "next 10 miles," &c.

a. Canterbury and Whitstable Railway, 7½d. per ton per mile; Blackfriars Junction 5d. per ton, with above terminals.

EXCEPTIONAL CLASS.

For articles of unusual length, bulk, or weight, or of exceptional bulk in proportion to weight; for articles requiring an exceptional truck, or more than one truck, or a special train; for locomotive engines and tenders, and railway vehicles running on their own wheels; for any wild beast, or any large animal not otherwise provided for; or for dangerous goods the companies take power to charge such reasonable sum as they may think fit in each case. Some of the companies fix charges ranging up to 10*d.* per ton per mile, with terminals extra.

SMALL PARCELS.

For small parcels not exceeding 560 lbs. in weight:—The *London and North-Western* propose, if such parcels are conveyed by merchandise train, to charge double the maximum rates for conveyance, and double the terminal charges authorised in respect of merchandise comprised in the 5th class of the classification, with a minimum charge as for 28 lbs. If conveyed by passenger train, 2*d.* per lb., with a minimum charge of 3*d.* per parcel. These charges are also proposed by the *Manchester, Sheffield, and Lincolnshire*. The *Great Northern* propose "such reasonable sum as the company may think fit," a proposal also adopted by the *London and South-Western* and all other companies, except as otherwise mentioned here. The *Cambrian Railways* adopt quite an intricate tariff in respect of these parcels. The *Lancashire and Yorkshire* propose the following rates:—

Maximum Rates for Conveyance.		Maximum Terminal Charges.		
In Weight.	For any Distance.	Station Parcel at each End.	Terminal Parcel at each End.	Service Parcel at each End.
Any parcel—	<i>s.</i> <i>d.</i>	<i>d.</i>	<i>d.</i>	<i>d.</i>
Not exceeding 7 lbs.	0 6	0½	0½	0½
Over 7 lbs. and not exceeding 14 lbs.	1 0			
" 14 " " " 28 "	2 0			
" 28 " " " 56 "	3 0	1	1	1
" 56 " " " 112 "	4 0	1½	1½	1½
And for every additional 112 lbs. or fraction thereof up to 560 lbs.	0 9	1½	1½	1½

For the charges of the *Cambrian and North Staffordshire* railways and of portions of other lines, the original paper must be consulted, which may be obtained, price 1*s.*, from the publishers of the *Ironmonger*, 42, Cannon Street, E.C.

THE REVISED CLASSIFICATION.

The following is the revised classification adopted by the railway companies, so far as it relates to the chemical industries.

CLASS "A" TRAFFIC.

Applicable to Consignments of Four Tons and upwards.

Cannel.	Culm.	Slack.
Cinders (coal).	Iron ore.	Slag or scoria (blast furnace).
Coal.	Ironstone.	
Coke.		

CLASS "B" TRAFFIC.

Applicable to Consignments of Four Tons and upwards.

Antimony ore waste; barytes, raw, in bulk; bog ore (or oxide of iron) for gas purifying; bricks, clay, common and fire; cement, in blocks or slabs; cement stone; chalk lime; clay in bulk, except otherwise herein provided; coal fuel, patent; coprolites and rock phosphate, unground; gambister; gas carbon; gas lime or gas-purifying refuse from gasworks; gypsum stone in lumps, unground; iron ore refuse for gas purifying; iron pyrites; lime, in bulk; limestone in bulk; red and purple ore; zinc ore.

CLASS "C" TRAFFIC.

Applicable to Consignments of Two Tons and upwards.

Antimony ore; arsenic; asphaltum; barytes, ground, in casks or bags; bricks, clay, glazed or enamelled; cement, except otherwise herein provided; chromate ore; clay, in bags or casks; copper ore; emery stone; ferro manganese; lead ore; manganese ore; mineral white; chloride of manganese; chloride of potassium; ochre; oxide of iron; pyrites, except otherwise herein provided; retorts, retort lids and mouthpieces, iron, or steel; skimmings (flux, lead, tin, or

zinc); slate, ground (for cement); spiegeleisen; sulphate of ammonia; sulphate of iron; sulphur, crude or unmanufactured; terra cotta blocks and bricks; umber; vegetable tar; whitening and whitening; zinc ashes; zinc carbonate (calamine); merchandise comprised in Classes "A" and "B" of the classification, if sent in quantities of less than four tons and not less than two tons.

CLASS 1 TRAFFIC.

Acetate of lead or sugar of lead; arseniate of soda; ashes, pot and pearl; bichrome and bichromate of potash, in casks; bottles, glass, black or green, common, packed; caustic potash; charcoal; chloride of zinc; copper precipitate; copper regulus; copperas; earth nuts or ground nuts; galvanised iron; lead ashes; litharge; nitrate of lead; paraffin, scale, and wax; plumbago ore; pumice stone; putty; resins (not oily); red lead; retorts (clay); resin; rotten-stone; saltpetre; silicate of soda; soap; solder; sulphate of copper; sulphur, except otherwise herein provided; tallow; tin ore; tin plates; washing powder and paste; weights, iron; white lead; zinc white or oxide of zinc; merchandise comprised in Classes "A," "B," and "C," if sent in quantities of less than two tons.

CLASS 2 TRAFFIC.

Antimony regulus; asbestos; black lead; blacking; borax; brass; bronze (phosphor) castings and ingots, rough; candles; cobalt ore; coir rope; colours, in casks or iron drums, or in tins packed in cases; copper; cotton and woollen waste; crucibles (clay); electric accumulators; electric insulators; emery; emery dust; filters, cast iron; iron liquor, or chloride of iron; ivory black; ivory waste or dust; nickel ore; nitrate of copper, in casks; nitrate of iron; oils, not dangerous, in casks or iron drums, except otherwise herein provided; paints, in casks or iron drums, or in tins packed in cases; plumbago; polishing paste; sal-ammoniac; silicate cotton or slag wool; size, except otherwise herein provided; tinfoil; tin liquor.

CLASS 3 TRAFFIC.

Anthracene, crude; beeswax; carbon candles, for electric lighting; carbonate of ammonia, in cases; chemicals (not dangerous, corrosive, or explosive), in casks, iron drums, bales, or bags; cinabar ore; colours, in cans, hampers, boxes, or iron bottles; delta metal; drysalteries, in casks; Dutch metal and leaf; electric batteries; filters, earthenware; glass, crown; glass, flint, except otherwise herein provided; glass, plate, rough; glue; gutta-percha, raw; lampblack; leather, except otherwise herein provided; nickel; paints, in cans, hampers, boxes, or iron bottles; pans, chemical and dye, iron or steel; silver ore; varnish; vegetable ivory; weights, brass.

CLASS 4 TRAFFIC.

Bronze powder; cobalt; drysalteries, except otherwise herein provided; earthenware, except otherwise herein provided; gold size; gutta-percha goods; india-rubber goods; oils, not dangerous, in cans, jars, and in bottles, in casks or boxes, except otherwise herein provided; stills, copper; vats; verdigris.

CLASS 5 TRAFFIC.

Aluminium; anthracene, except otherwise herein provided; bismuth; colours, in jars; crucibles, except otherwise herein provided; empty cases, casks, crates, hampers, and other empties, except otherwise herein provided; glass, plate, silvered; glass, stained; magnesium metal; nitrate of copper, in jars or stone bottles, covered with wicker basketwork; paints in jars; quicksilver; silver precipitate; sponges; thermometers; ultramarine; and, subject to the provisions of the Railway and Canal Traffic Act, 1888, all articles, matters, and things not herein-before classified, and not being of an explosive or dangerous character.

In addition to the revised classification each railway company has filed a revised schedule of maximum rates and charges, with a formal statement of the general conditions which are proposed to govern the traffic over its system. As these general conditions are not identical in every instance, and as they are of much importance, we have compared them with each other, and give the results of that comparison below. In doing so we take the *London and North-Western* as the standard, and note the variations from it of the other principal companies under, or in connexion with each clause or section. Where no variations are specially mentioned it may be taken for granted that all the chief companies are in substantial agreement with the *London and North-Western* schedule.

GENERAL CONDITIONS.

Each company defines what is meant by the words "the company," mentions the lines which are leased by it; defines the term "merchandise" to mean goods, cattle, live stock, and animals of all description; defines the term "trader" to mean any person sending, receiving, or desiring to send merchandise by the railway; and defines the word "terminal station" to mean a place at which the company have provided accommodation for receiving or delivering merchandise from or to traders, but does not include a junction between the railway and a siding not belonging to the company.

The term "large towns" mentioned by each company in respect of terminal charges is specified in each case, with "any other places on the railway which may from time to time be added thereto by authority of Parliament."

The "large towns" mentioned by the principal companies are:—
London and North-Western.—London, Liverpool (including Bootle), Manchester (including Salford), and Birmingham.

Great Western.—London, Liverpool, Manchester, and Birmingham.

South-Eastern.—London and places near it which are within "an urban district" under the Cheap Trains Act, 1883.

London, Brighton, and South Coast.—London and its "urban districts."

Great Northern.—London.

North British.—Dundee, Edinburgh, Glasgow, and Leith.

Lancashire and Yorkshire.—Liverpool, Bootle, Manchester, and Salford.

Manchester, Sheffield, and Lincolnshire.—Manchester, Ashton-under-Lyne, Oldham, Barnsley, Sheffield, Rotherham, Hull, and Grimsby.

London and South-Western.—London and its "urban districts."

Midland.—London, Liverpool, Manchester, and Birmingham.

Great Eastern.—London.

Caledonian.—Aberdeen, Dundee, Edinburgh, Glasgow, Greenock, Leith, and Paisley.

London, Chatham, and Dover.—London and its "urban districts."

Cambrian.—None.

Furness.—None. Terminals apply to "any station."

North-Eastern.—None. Terminals are simply "station terminals."

Glasgow and South-Western.—Glasgow, Paisley, and Greenock.

North Staffordshire.—None.

The maximum rates and charges proposed to be authorised are divided as follows:—

1. Maximum rates for conveyance.

2. Maximum station terminals.

3. Maximum service terminals.

To these the other companies add:—

4. Special charges.

(1.) *Maximum rates for conveyance* include:—

(a.) The charge for conveying merchandise by merchandise train along the railway.

(b.) The provision of trucks, except for merchandise comprised in Class A of the classification; the following articles in Class B:—Clay, in bulk; gas lime or gas-purifying refuse, from gasworks; lime, in bulk; nightsoil; salt, in bulk; sand, in bulk; and the following articles in Class C:—Creosote (coal tar), coal tar or gas tar, and gas water.

The other companies put this in a different way, but the meaning of all is that trucks are provided for all traffic except for the goods named.

(2.) *Maximum station terminals* include the charge for accommodation (exclusive of coal drops) at terminal stations provided by the company for dealing with merchandise as carriers thereof, before and after conveyance, together with the following services and expenses, namely:—Share of general charges and office expenses, attributable to such services as are rendered by the company to all descriptions of merchandise alike in performing the duties incidental to the business of a carrier: shunting and marshalling of trucks; and the provision of engines, horses, machinery, plant, and stores used in the services referred to in this sub-section.

(3.) *Maximum service terminals* include the charges for the following services rendered by the company in dealing with merchandise as carriers thereof, before or after conveyance, namely:—The labour of servants of the company in loading or unloading, covering or uncovering merchandise, the provision of machinery, plant, sheds, or stores used in such services, and also the share of general charges and office expenses specially attributable to the classes of merchandise in respect of which service terminals are authorised.

(4.) *Special charges*.—The company may charge such reasonable amounts as, in case of difference, shall be determined by the Railway Commissioners in respect of the following matters:—

(a.) Accommodation provided by the company at or in connexion with sidings not belonging to the company, and the delivery or reception of traffic to and from such sidings.

(b.) The collection or delivery of merchandise.

(c.) The use of trucks, or the use or occupation of any accommodation included in the station terminal, beyond such period before or after conveyance as shall be reasonably necessary for enabling the company to deal with merchandise as carriers thereof, and the services rendered in connexion with such use or occupation.

(d.) The loading or unloading, covering or uncovering merchandise included in Class A or Class B of the classification.

For further special charges by individual companies, the original paper must be consulted.

PROVISIONS AND REGULATIONS.

1. For any distance not exceeding six miles the company may charge the rates authorised for six miles.

2. For any quantity in one truck received from or delivered on or at a siding not belonging to the company, may be charged as for a reasonable minimum load.

3. A fraction of a quarter of a ton shall be deemed a quarter of a ton, and larger fractions of a ton shall be charged for according to the number of quarter-tons in them.

4. Miles are treated similarly to the above.

5. For fractions of a penny the company may demand a penny.

6. Imperial avoirdupois weight shall be used.

7. Articles sent in quantities, although in separate parcels, such as bags of sugar and the like, shall not be deemed small parcels.

Individual companies mention further provisions and regulations beyond those above mentioned, which are virtually identical in all the schedules, but the original paper must be consulted for details of these.

THE NEW RAILWAY RATES.

Form of Notice of Objection.

The Board of Trade has fixed the following as the official form of objection to the classification and proposed new rates and charges of the railway companies. The notice must be written upon foolscap paper.

RAILWAY AND CANAL TRAFFIC ACT, 1888.

TO THE BOARD OF TRADE:—

I, the undersigned [*fill in Christian and surname of objector*], hereby give notice that I object to the parts of the proposed classification of merchandise traffic and schedule of rates and charges of the _____ company set forth in the first column of the schedule to this notice, on the ground set forth in the second column of this notice, and that my address, to which all notices and communications may be sent, is [*here state address of objector in full*].

Dated the _____ day of _____ Signed _____

SCHEDULE.

Reference to Proposed Classification and Schedule.	Grounds of Objection.
--	-----------------------

Every notice of objection must be signed by the person making the objection, or where the objection is by a company or body or association of persons, by some person or persons on behalf of the company, body, or association, and must state a postal address to and at which notices may be served or communications addressed to the objector or objectors. The envelope or cover enclosing each notice of objection must be marked outside "Railway and Canal Traffic Act, 1888."

A copy of every notice of objection must at the same time be sent to the secretary of the company affected thereby, by prepaid letter, addressed to the company at its principal office.

UNITED STATES MINERAL STATISTICS FOR 1888.

(From the Engineering and Mining Journal.)

THE MINERAL INDUSTRIES IN 1888.

The year just closed has been a very eventful as well as a very prosperous one to the mineral industries. The value of the mineral products, which in 1887 amounted, as shown on another page, to the enormous total of \$4,284,225,000, was still further increased in nearly every item in 1888, when it undoubtedly exceeded \$50,000,000,000, or more than the aggregate value of the mineral products of all European countries.

PRODUCTION.

Gold. Troy ozs.	1,650,000
Coining value, 20'67 dols. per oz.	34,105,500

UNITED STATES IMPORTS AND EXPORTS OF COPPER.

From official data we get the exports of copper for 11 months from all parts of the United States, and we have added the exports for December from the Port of New York. We have carefully estimated the copper in ore, matte, &c., exported, and thus estimate the total exports as about 78,000,000 pounds. The imports were mostly in ore, which produced, as already stated, 5,000,000 pounds of copper.

* Evidently errors in quantities.

PRODUCTION OF ZINC IN THE UNITED STATES IN 1888.

The production of spelter in the year 1888 amounted to 57,000 short tons, of which 10,400 tons was produced in the Eastern and Southern States, about 22,500 in Illinois, and the balance in Kansas and Missouri. This has been a moderate increase over last year, and the mines are reported in good condition and likely to increase the output in 1889.

1888	636,449	121,822

IRON STATISTICS.

We compile the following estimates of production for 1888 from the bulletin of the American Iron and Steel Association, the best authority on the subject:—

	1888.	1887.
Production of pig-iron	Gross Tons. 6,000,000	Gross Tons. 5,417,118
„ Bessemer rails	1,350,000	2,101,904
„ Lake Superior iron ores	5,000,000	4,738,203
Imports of iron ores	600,000	1,194,301
„ iron and steel	950,000	1,783,251

UNITED STATES NITRATE STATISTICS.

The shipments to Europe, including the large quantity loading December 1st, would be 670,000 tons, against 610,000 tons last year. There will be more than this difference in the spring supply, because engagements are made for steamer shipments in January. The increased supply has given the bears on the other side an opportunity, but it is a question how long they will have the markets. Beside the growing general use of nitrate as a fertiliser of the highest rank, the advancing value of beet sugar justifies the belief that a larger acreage of beet culture will be found this year, and perhaps to an extent that may give the market another squeeze.

The shipments to the States were 472,500 bags, against 555,000 bags in 1887, 522,750 in 1886, 270,325 in 1885, and 437,234 in 1884. The quantity to arrive for Atlantic ports is 224,000 bags, against 239,000 in 1888, 238,500 in 1887. The total visible supply is 310,000 bags, against 301,940 in 1888, 311,236 in 1887. The quantity to arrive in Europe is 2,527,000, making the visible supply there 3,112,000 bags, against 2,927,500 bags in 1888, and 2,070,000 in 1887. The deliveries at San Francisco during last year were 60,000 bags, making total deliveries in this country 515,000 bags, against 534,347

in 1887, 151,761 in 1886. In Europe the deliveries were 4,712,000 bags, making total for the world 5,227,000, against 4,161,347 in 1887, 3,522,260 in 1886, 3,278,986 in 1885, and 3,971,071 in 1884.

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

1888.

18,289. J. Neilson and J. Whitclaw, Glasgow. Improvements in gas and air reversing valves for regenerative and other furnaces, &c. December 14.

18,312. W. Booth, Manchester. Improvements in furnaces. December 15.

18,383. W. R. Watson and R. A. Robertson, Glasgow. Apparatus for evaporating, concentrating, and distilling liquids. December 17.

1889.

1078. H. Green and A. Green, Manchester. Purifying water, and removing crustation from steam boilers. January 21.

1202. A. H. Hobson, London. Apparatus for use in making extract from, and otherwise treating, partially soluble substances by means of steam pressure and heat. January 22.

1345. B. Nicholson and T. Palmer, London. Cylinders or rotating vessels for use in tanning or otherwise treating hides or skins, washing, emulsifying, churning, or like operations; applicable also for the treatment of materials in vacuo or under fluid pressure or the like. January 24.

1424. C. F. H. Hayes, Stratford. Apparatus for compressing air, gases, or other fluid, and for force pump purposes generally. January 25.

1462. E. Ducretet, London. Filtering apparatus. January 26.

1847. E. Harrison, London. Means and apparatus for softening and purifying water, and for the removal and prevention of incrustation in steam and other boilers. February 1.

2036. W. Sayer, London. Apparatus for forcing, exhausting, or pumping air, gases, liquids, and the like. Complete Specification. February 5.

2259. J. Simpson and S. Reid, London. Apparatus for economising coal and for the better combustion of smoke in furnaces. February 8.

2528. W. Hicks, London. Improved centrifugal separator for removing solids and other matter from liquids. February 13.

2603. W. Beaumont, London. Improvements in centrifugal pumps. February 14.

2677. W. F. Gorham and M. Watson, Newcastle-on-Tyne. Improvement in arrangement of mills for grinding cement, phosphates, and other substances. February 15.

2691. C. Hill, London. Improvements in the grates of furnaces employed in connexion with brewers' cuipers, salt pans, boilers, &c. February 15.

2736. J. Wood, Bradford. Method and apparatus for consuming smoke. February 16.

COMPLETE SPECIFICATIONS ACCEPTED.*

1888.

2548. F. Windhausen. Refrigerating apparatus, applicable to machines for compressing air and gases. February 20.

2549. F. Windhausen. Refrigerating apparatus, applicable to machines for compressing air and gases. February 20.

3044. O. Bran. Centrifugal machines. January 30.

3123. T. Burtenshaw. *See* Class II.

4139. J. J. Hicks. Apparatus for ascertaining the specific gravity of liquids. January 30.

4766. S. H. Johnson and C. C. Hutchinson. Filter presses. February 6.

5246. J. H. Breze. Apparatus for condensing, cooling, and heating fluids; and machinery for the construction thereof. February 13.

5426. J. S. Sawrey and H. Collet. Apparatus for separating liquids from solid matters in suspension. January 30.

5527. R. Le Las and A. Robin. Apparatus for supplying furnace fires with moistened air. February 20.

16,761. R. Reichling. Apparatus for condensing steam and for heating and purifying feed water. February 6.

17,012. R. Hasenclever. Apparatus for subjecting pulverulent or granular materials to the action of gases. January 16.

18,925. D. McColey Weston. Centrifugal machines. January 16.

18,939. N. L. Hilton. Improved agitators. February 6.

18,860. H. J. Allison.—From The Casamajor Filter Co. Apparatus for cleansing filtering media. February 20.

1889.

785. H. H. Lake.—From J. M. Duncan. Apparatus for evaporating brine, &c. February 20.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

1888.

18,451. E. Brook and J. J. Brook, London. Regenerative kilns. December 18.

18,665. J. F. Cohen, London. Improvements in the manufacture of artificial fuel. December 18.

1889.

1210. J. Williams, London. A reverberating cupola furnace, and gas, tar, and crude petroleum-making apparatus. January 23.

1271. H. Simon, London. Improvements in coke ovens. January 23.

1326. J. Greenfield.—From C. A. d'Assumpcao and E. S. Dias, Portugal. Improvements in the treatment of coal and small coke or breeze in the manufacture of gas and coke. January 24.

1444. L'Agence Maritime Anglaise, Limited.—From C. Audony, France. Apparatus for manufacturing artificial fuel blocks. January 25.

1508. L. H. Green, London. Improvements in or applicable to gas retorts and ovens. Complete Specification. January 28.

1637. J. Ewing, Stoneycroft, Liverpool. Combustion and economy of fuel, and bar preservation. January 30.

1806. C. H. Mowll, London. An improved composition of artificial or block fuel. February 1.

1846. W. Borzett, London. Improvements in the application of heat produced from liquid hydrocarbon and water burners to the production of light and electricity, and in apparatus for this purpose. February 1.

1955. W. Wells, Leith. An improved form of burner for converting oils or spirits into vapour or gas to obtain light or heat. February 4.

2093. J. F. M. Pollock, Leeds. Improvements in machinery for the manufacture of blocks of compressed coal dust and pitch or other agglomerate; also of clay, cement, and similar substances. February 6.

2246. G. H. Lloyd, A. L. Lloyd, H. Bewlay, and W. S. Sutherland, Liverpool. Improvements in producing water gas, and in apparatus therefor. February 8.

2351. J. Hillier and G. H. Rayner.—For Messrs. Rayner and Cassell, London. An improved fuel, which burns without smoke or smell. February 9.
2378. M. Murphy and T. J. Cluff, Dublin. Making gas from paraffin oil on an improved method, and utilising same for heating purposes and propelling power. February 11.
2508. H. S. Maxin, London. Improvements in and relating to apparatus for carburetted gas. February 12.
2561. J. Pring, Newport. Improvements in machinery or plant for the manufacture of patent fuel. February 13.
2659. J. C. Chandler, London. Improvements in apparatus for washing and scrubbing gas. February 14.
2664. J. O. Spong, London. Novel means and apparatus to facilitate the enrichment and purity of flame of coal gas. February 14.
2796. H. Darby, London. Improvements in apparatus for generating and burning gases from hydrocarbon oil and water. February 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

1195. J. T. Williams. Treating small anthracite coal to render it available for use as fuel.
3179. E. Bowen. Treating the by-products of gas and tin-plate manufactures. January 16.
3423. T. Birtenshaw. "Tar-burners," and the furnaces to which they are applied for heating gas retorts, &c. January 30.
3495. A. McDougall. Apparatus for manufacture of gas. January 16.
3538. G. Seagrave and P. A. Olivier. Apparatus for the carburization of gas or air. January 16.
3566. R. Dempster and J. Dempster. Apparatus for feeding retorts with coal, &c. January 23.
3880. E. B. Ellice-Clark and L. Clark. Apparatus for obtaining oxygen and nitrogen from air. January 16.
3917. R. Auton. Making blocks of compressed fuel. January 23.
3950. R. Auton. Making blocks of compressed fuel. January 30.
3992. L. T. Wright. Means for indicating the extent to which gasholders are charged. January 23.
4158. R. B. Avery. Apparatus for generating and burning gaseous fuel. January 23.
4162. J. H. Glew. Compound of materials for production of firelighters. January 23.
4885. J. H. R. Dinsmore. Manufacture of gas from coal. February 6.
5259. J. V. Capeck. Electrical heating. February 13.
6220. W. A. McIntosh-Valon and Brin's Oxygen Co., Limited. Purification of carburetted hydrogen or coal gas. February 13.
- 17,562. De Witte Stearns. Apparatus for production of gas from liquid hydrocarbon, and devices for utilisation of gaseous fuel. January 16.
- 18,027. W. T. Bate. Apparatus for manufacture of gas. February 6.
- 18,105. T. Shaw. Apparatus for testing and detecting the presence of gases or gaseous mixtures. February 13.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

APPLICATIONS.

1889.

2096. R. F. Craig, Glasgow. Improvements in and connected with retorts and apparatus for decomposing and distilling products from wood, shale, or other material. February 6.
2569. J. H. du Vivier, London. Improvements in apparatus for the production of pyroligneous acid. February 13.

COMPLETE SPECIFICATION ACCEPTED.

1888.

566. R. Dempster and J. Dempster. See Class II.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

1888.

- 18,425. S. Pitt.—From L. Casella, Germany. Manufacture of bluish-black colouring matters. December 17.
- 18,524. B. Wilcox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of succinic acid, rhodamine, or rhodamine succinate. December 18.

1889.

1257. O. Overbeck, London. Improvements in the manufacture of colouring matter. January 23.
1303. R. Lucas, London. Improvements in the manufacture of phthalic acid. January 24.
1518. O. Imray.—From The Society of Chemical Industry, Switzerland. Manufacture of monoacetylmetaamidophenol. January 28.
1523. J. G. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. Improvements in the manufacture of alpha-naphtholdisulphonic acids, and for the obtaining therefrom of materials suitable for dyeing and printing. January 28.
1735. A. Banz.—From Messrs. Dahl and Co., Prussia. Improvements in dye-stuffs or colouring matters. January 31.
1771. B. Wilcox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture or production of para-amidophenol and the formyl combinations thereof. January 31.
1803. J. Frost, Halifax. Improvements in the method of and means for concentrating or evaporating and distilling solutions for the production of dyes and other bodies. February 1.
1844. A. G. Green, London. Improvements in the manufacture of primuline. February 1.
1992. C. Dreyfus, London. Improvements in the production of colouring matters for dyeing. February 4.
2360. E. Brasier and J. H. Knowles, London. The production of a new colouring matter, extract, or dye and tannin solution obtained in the process of treating certain fibrous materials. February 3.
2499. O. N. Witt, London. The production of new azo-dyes applicable for dyeing and printing. February 12.
2635. R. Gnehm, London. A new colouring matter for dyeing and printing purposes, and its method of manufacture. February 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

1533. H. H. Leigh.—From R. G. Williams. Manufacture of colouring matters. January 16.
4217. W. P. Thompson.—From The Actien Gesellschaft für Chemische Industrie, Rheinau. Manufacture of colouring substances by the reaction of aromatic hydrazin sulphonic acids on retenehiou. January 23.
4476. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik. Manufacture of blue colouring matters. February 6.
4625. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation, Berlin. A new alpha-naphtholdisulphonic acid. January 30.
5404. H. H. Leigh.—From R. G. Williams. Colouring matters. January 16.
5852. S. Pitt.—From L. Casella and Co. New blue colouring matters. February 20.
5910. C. D. Abel.—From The Actien Gesellschaft für Anilin Fabrikation, Berlin. Azo-colouring matters. February 6.
6143. H. H. Leigh.—From R. G. Williams. Colouring matters. January 16.
6899. L. Limpach. Separating isomeric xylylides from commercial xylyline in a pure state, for production of colouring matters. February 20.
- 15,654. H. H. Leigh.—From R. G. Williams. Azo-colouring matters. February 20.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

1889.

2256. I. Frankenburg, Manchester. Improvements in the manufacture of waterproof fabrics. February 8.
2570. J. H. du Vivier, London. A new composition termed "artificial silk" for the production of the threads or filaments and films, and for coating threads, fabrics, or objects, and apparatus employed in the manufacture of said composition. February 13.
2571. J. H. du Vivier, London. Improvements in apparatus for the manufacture of textile threads from viscous or semi-fluid matters. February 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

2391. D. W. Pessey. Making sewing threads from lubricated or coated yarns. January 23.

4786. J. Petrie and F. W. Petrie. Apparatus for cleansing wool and other fibrous materials. February 6.

12,682. J. Mactear. Treating vegetable fibrous material for obtaining fibre therefrom. February 13.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

1888.

18,252. J. Clegg, Liverpool. Improvements in cleansing, scouring, bleaching, mordanting, and dyeing cotton yarn in the bundle form in which it is sold, and apparatus therefor. December 14.

18,348. S. D. Stead, London. Improvements in and machinery for washing, scouring, and bleaching of fibrous materials. December 15.

18,517. H. F. Lippett, London. Hollow perforated tubes for dyeing, bleaching, or otherwise treating yarn in cops. Complete Specification. December 18.

1889.

1172. W. Mather, London. Improvements in apparatus for treating textile materials with liquids, gases, or vapours. Complete Specification. January 22.

1313. E. M. H. Andreoli. See Class XI.

2690. T. Wolstenholme, London. An improved machine for dyeing yarns. Complete Specification. February 5.

2525. H. Erdmann, Halle, Germany. A cold process of dyeing hair and feathers by means of paraphenyldiamine or similar bases. February 13.

2668. J. Walker and H. Carver, Manchester. Improvements in printing what are known as "sanitary" or "washable" paper-hangings. February 15.

2743. F. A. Blair, Glasgow. Improvements in and connected with vats or apparatus for dyeing, washing, bleaching, scouring, or mordanting fibrous materials. February 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

1357. T. Winter. Immersion rollers used in dyeing, bleaching, sizing, &c. January 16.

2322. W. P. Thompson.—From A. Douleiron and E. van Meerbeeck. Apparatus for cleansing, dyeing, or steeping fabrics. February 6.

3490. W. Mycock. Dyeing apparatus. January 30.

17,271. F. E. Anderson and S. Hodgeson. Method and apparatus for dyeing, scouring, and washing wool, &c. January 16.

18,717. E. O. Fankhauser. Mordant for dyeing purposes. February 20.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

1888.

18,320. S. B. Bowen, Liverpool. Improvements in or relating to the concentration of sulphuric acid, and in apparatus therefor. December 15.

18,573. E. Solvay, London. Improvements in the purification of gases. December 19, but antedated (under sec. 103, Pat. Act, 1883) June 5, 1888, being date of application in Belgium.

18,574. E. Solvay, London. Improvements in the manufacture of chlorine and chloride of lime, and in apparatus therefor. December 19, but antedated (under sec. 103 of Pat. Act, 1883) June 5, 1888, being date of application in Belgium.

1889.

1110. F. Maxwell-Lyte, London. Improvements in the production of chlorine, of hydrochloric acid, and of certain subsidiary products. January 21.

1189. E. Ange, London. Improvements in the manufacture of salts of alumina. Complete Specification. January 22.

1376. E. W. Parnell, Liverpool. Improvements in the manufacture of calcium sulphhydrate solution from calcium sulphide or Leblanc waste. January 25.

1769. P. McLaren, Glasgow. An improved process of and means for manufacturing brown sugar of lead. January 31.

1885. C. Roth, London. Improvements in the manufacture of nitrate of ammonia, and sulphates, chlorides, and carbonates of potassium and sodium. February 2.

1916. H. Y. Castner. See Class X.

1989. H. Y. Castner. See Class X.

2160. L. Mond, Liverpool. Improvements in apparatus for volatilising ammonium chloride. February 6.

2161. F. Gilleteaux, London. Improved process for decomposing hydrochlorate of ammonia. February 6.

2310. T. Parker and E. Robinson, Manchester. Improvements in and relating to the production of chlorine, and to the manufacture of sulphate of soda. February 9.

2383. T. Parker and E. Robinson, Manchester. Improvements in the manufacture of cyanogen compounds from sulpho-cyanides. February 11.

2575. L. Mond, Liverpool. Improvements in volatilising ammonium chloride, and in obtaining ammonia, chlorine, and hydrochloric acid therefrom; also in obtaining chlorine from hydrochloric acid. February 13.

2608. J. McBryde and A. Kay, Liverpool. Improvements in the manufacture of chlorates. February 11.

2656. F. W. Dapre, London. An improved process of manufacturing potassium carbonate. February 14.

2786. E. K. Muspratt and G. Eschelman, London. Improvements in the manufacture of chlorates, and of magnesium hydrate for use therein. February 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

2831. E. W. Parnell and J. Simpson. Treating sulphide of calcium for obtaining sulphide of ammonium and sulphuretted hydrogen. January 23.

3118. J. S. Rigby. See Class IX.

3128. H. Green. Apparatus for treating ammoniacal liquor. February 6.

3678. A. M. Clark.—From J. B. Daguin. Manufacturing soda by means of ammonia, and producing carbonate of soda, caustic soda, and hydrochloric acid or chlorine. January 23.

3699. A. M. Clark.—From J. B. Daguin. Facilitating the oxidation of sulphurous acid for the manufacture of sulphuric acid, and of hydrochloric acid and chlorine. January 30.

4648. E. W. Parnell and J. Simpson. Producing sulphur from sulphuretted hydrogen. February 13.

4699. W. D. Bohm. Apparatus for the expulsion of chlorine or other noxious gases from solutions. February 20.

6175. E. W. Parnell and J. Simpson. Production of sulphur from sulphuretted hydrogen. February 13.

11,920. C. A. Faure. See Class X. February 20.

17,945. G. C. Dymond. From C. E. D. Winssinger. Manufacturing bicalcareous phosphate, called precipitated phosphate. January 30.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

1888.

18,303. W. Ambler, London. Improvements in or applicable to the manufacture of cylindrical and tubular articles of plastic clay and other plastic material. December 14.

18,457. W. A. Sheppard, London. An improved machine for the purpose of washing and refining fuller's earth, china clay, and other similar substances. December 18.

18,577. W. H. Turner, London. Improvements in or relating to painting or printing upon earthenware. December 19.

18,622. J. Bessley, Coventry. Improvements in glassware, earthenware, and the like. December 20.

18,661. W. W. Macvay and R. Sykes.—From H. M. Ashley, United States. Improvements in the manufacture of bottles and other hollow ware in glass, and in apparatus to be used therein. December 20.

1889.

1079. G. Vernon, Birmingham. An improved method of illuminating or ornamenting pottery ware and glass. January 21.

1198. A. Ramsden, London. Improvements in the method of and machinery for making earthenware pipes. January 22.

1377. A. Larthe, Dresden-Langton. Applying the style of enamels, hitherto applied to copper, to porcelains, earthenware, and crystal glass. January 25.

1822. W. H. Turner, London. Improvements in the manufacture of articles of pottery. February 1.
 2337. G. Emberson, London. Improvements in producing ornamental effects on glass or like transparent material. February 9.
 2641. T. Davidson, London. Improvements in the manufacture of articles of pressed glass. February 14.
 2776. J. Thorne, London. Improvements in the manufacture of coloured lenses for signal and other lamps. February 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

1550. J. P. Guy. Machine for making hollow earthenware. January 30.
 2318. J. B. Adams. Manufacture of bottles and other glassware, and apparatus therefor. February 13.
 3583. J. Holroyd and A. Wilson. Gas-fired kilns for burning pottery, &c. January 23.
 3743. G. M. Garrard. Roofing and wall or hanging tiles, and dies and presses for moulding such tiles. February 13.
 4204. A. Taylor and N. Brooke. Method and apparatus for moulding and pressing earthenware and fireclay baths, sinks, basins, closets, &c. February 13.
 4777. T. Button and J. Binner. Machine for chipping glass marbles or stoppers for glass bottles. January 23.
 5214. W. D. Gooch, F. H. Varley, and F. B. Lidstone. Manufacture of porous artificial stone for use as indestructible wicks, filter, partitions, &c. February 13.
 5253. F. Beer. Plastic composition for moulding. February 6.
 6039. W. Ambler, J. Rhodes, and S. Rhodes. Manufacture of glass bottles. January 16.
 15511. M. Winter. Manufacture of brilliant crystal coloured flowers. February 6.
 16737. T. Soufflet-Leban. A new mosaic tile. February 13.
 18101. P. A. Newton.—From J. Henning and F. Wrede. Manufacturing bottles or other hollow bodies of glass, and apparatus therefor. January 23.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

1888.

18182. G. S. Hüek and H. R. Schuck, London. Improvements in artificial stone. December 18.
 18491. W. Joy, London. Improvements in apparatus for use in the preparation of slurry for the manufacture of cement, and in mixing slurry with fuel. December 18.

1889.

1082. J. Robinson, London. A quick-drying adhesive cement for the better fixing of enamelled copper letters, designs, or devices, or other letters or designs, to glass, metal, wood, or stone. January 21.
 1262. A. McLean, London. An improved mode of and means for manufacturing blocks of artificial stone. January 23.
 1765. L. Brentini, London. Improvements in roofing tiles. Complete Specification. January 31.
 1952. J. C. Merryweather, London. Improvements in paving. February 4.
 2093. J. F. M. Pollock. See Class II.
 2121. G. A. Wright, London. An improved block, tile, or slab for building and other purposes. February 6.
 2289. J. Homan, London. Improvements in fireproof structures, and in bricks for the same. February 8.
 2403. J. H. Hughes, London. Improvements in the manufacture of a fireproof material which can be used for decorative, building, artistic, sanitary, and other purposes. February 11.
 2632. J. Sazden, London. Improvements in artificial building materials. Complete Specification. February 14.
 2718. A. C. Ponton, B. L. Mosely, and C. Chambers, London. Improvements relating to the preparation of siliceous materials used in the manufacture of artificial stone. February 15.
 2780. A. C. Ponton, B. L. Mosely, and C. Chambers. Improvements in artificial stone. February 16.
 2781. A. C. Ponton, B. L. Mosely, and C. Chambers. Improvements in and relating to the manufacture of artificial stone. February 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

1515. C. A. Eissner. Machines for cutting clay, for making bricks and tiles, &c. January 30.
 2632. J. Robertson and J. A. Patrick. Manufacture of Portland or similar cement. January 23.
 3118. J. S. Rigby. Manufacture of cement, and utilisation of the lime-mud residue of the ammonia-soda process therefor. February 20.
 18708. E. Edwards.—From F. Meyer. Waterproof roofing material. February 13.
 18596. F. Hunsinger. Improved roofing tile. January 30.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

1888.

- 17611A. B. J. B. Mills.—From T. A. Edison, United States. Improvements in the method of and apparatus for effecting the separation of metals from their ores by mechanical means.—Originally included in No. 17,614 of December 3.
 17611B. B. J. B. Mills.—From T. A. Edison, United States. Improvements in the method of and apparatus for extracting gold from its ore by amalgamation.—Originally included in No. 17,614 of December 3.
 18290. A. H. H. Bratt, Plumstead. The production of steel or metal ingots for gun and other forgings with freedom from blow-holes or cavities, and with equal distribution of metalloids through their masses. December 14.
 18263. J. L. M. Alkings and F. Mazalon, London. Improvements in or relating to the suppression or neutralising of the effects of deleterious gases in pits and underground workings. December 14.
 18400. T. Turner, Birmingham. The treatment of dross from the tin orterne plate manufacture. December 17.
 18440. C. A. Burghardt, Manchester. Improvements in the production of pure zinc. December 18.
 18477. G. C. Dymond.—From W. H. Appleton, United States. Improvements in machines for rolling seamless tubing, columns, and other hollow articles from hollow ingots. Complete Specification. December 18.
 18492. T. H. Roberts, London. An improvement or improvements in treating the tap cinder produced in puddling iron. December 18.
 18493. R. A. Hadfield, London. Improvements in cutting hollow steel and other steel shells, and in appliances therefor. December 18.
 18506. R. A. Hadfield. Improvements in the manufacture of hollow steel and other steel shells. December 18.
 18529. J. Mactear, London. Improvements in the production of sodium, potassium, aluminium, and alloys of aluminium. December 18.
 18551. J. Wilson, Berwick-on-Tweed. Treating the waste liquor of copper works. December 19.
 18632. T. Summers, London. Improvements in cleaning tin,terne, or other metal plates, and apparatus therefor. December 20.

1889.

1062. W. Corbett, W. W. Manfield, and J. Marsh, Manchester. Improvements in and relating to the manufacture of iron and steel. January 21.
 1099. J. Richardson, London. Improvements in the manufacture of iron and steel. January 21.
 1230. W. E. Pedley and T. G. Barlow, Massicks, Old Brompton. Improvements in cooling and breaking up slag. January 23.
 1380. J. Müller, Manchester. Miners' safety lamps. January 25.
 1406. W. S. Simpson, London. A novel process or means for the production of wrought metal articles direct from semi-fluid metal, and furnaces and moulds for the purpose. January 25.
 1418. G. Kruss, London. A process for decomposing technical nickel and its salts, and galvanically coating objects with pure nickel. Complete Specification. January 25.
 1531. D. Whitehouse, London. Improvements in the manufacture of tin andterne plates, and in machinery therefor. January 28.
 1590. W. E. Koch, London. Improvements in apparatus for casting steel pipes. Complete Specification. January 29.
 1602. M. Johnson, W. E. Field, and J. S. Beeman, London. Certain improvements in the amalgams and method of applying the same used in amalgamation of gold and silver, called or intended to be called "Johnson, Field, and Beeman's patent amalgamating process." Complete Specification. January 29.
 1622. J. Young, Glasgow. Improvements in obtaining gold and silver from ores and other compounds. January 30.

1629. W. H. Duncan, Coalbrookdale. Improvements in extracting, washing, and separating gold, silver, diamonds, copper, and other metals from the earthy matter in which they are found. January 30.

1762. Sir Lowthian Bell, London. Improvements in the manufacture of steel by the open-hearth process. January 31.

1916. H. Y. Castner, London. A process for the production of pure double chlorides of aluminium. February 2.

1957. J. Ward, Glasgow. Improvements in and relating to the manufacture of compound plates of steel and iron. February 4.

1989. H. Y. Castner, London. A process for the production of pure double chlorides of aluminium. February 4.

2031. S. McGilley Godfrey and J. B. Allen, London. Impregnating metals and making metal alloys. Complete Specification. February 5.

2078. H. M. Redemann and R. J. Tilford, London. Improvements in and relating to a new and useful process for treating crude or low grade steel to produce a refined or high grade steel. Complete Specification. February 5.

2080. H. M. Redemann and R. J. Tilford. Improvements in and relating to a new and useful process for treating crude or low grade steel to produce a refined or high grade steel. Complete Specification. February 5.

2070. H. M. Redemann and R. J. Tilford. Improvements in and relating to a new and useful process for treating crude or low grade steel to produce a refined or high grade steel. February 5.

2174. J. Hill, London. Improvements in the manufacture of steel ordnance. February 7.

2279. A. J. Boulton.—From O. Hofmann and P. Linke, Germany. Metal alloy for moulders' tools. Complete Specification. February 8.

2372. A. G. D. Craushay, London. Improvements in the manufacture of chain made of steel, iron, or other metals. February 9.

2350. T. Bell, London. An improved method of lining barrels or other vessels to resist acids for use in extracting metals by chlorination or similar process from their ores. February 9.

2369. L. Roberts, J. Jones, and the Moor Steel and Iron Company, Limited, Stockton-on-Tees. An improved method of and apparatus for delivering and charging pig iron and "scrap," or other heavy material, into steel and open-hearth furnaces. February 11.

2377. A. C. A. Holzappel, London. Improved machine for flanging and shaping steel, iron, and other metal plates for ship-building and other purposes. February 11.

2359. A. Heine, London. Improvements in kilns for the calcination of copper ore and regulus from 25 to 45 per cent. of copper. February 11.

2456. W. Hawdon, London. Improvements in apparatus for removing molten slag or scoria from furnaces. February 12.

2483. R. Welford, Harrow. Improvements in obtaining gold, silver, and copper from ores and other compounds. February 12.

2538. W. J. Dobbs, T. Dobbs, and J. Dobbs, Wolverhampton. Improvements in the method of ensing or coating iron or other metallic tubes with brass or other sheet metal. February 13.

2704. E. J. Ball, London. Improvements relating to the manufacture of iron and steel. February 15.

2722. E. L'Homme, London. Improvements in certain metallic alloys. February 15, but antedated (under Patent Act, 1883, sec. 103) July 19, 1888, being date of application in Belgium.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

652. F. Herbert, J. E. Jordao, and C. G. Jordan. Cast-iron, steel, and other spigot and flange pipes. January 23.

814. P. Jensen.—From F. W. Martin. Process and apparatus for the manufacture of plates, sheets, &c. of copper, yellow-metal, naval brass, &c. January 23.

885. J. Otter, Crane for lifting and turning over large ingots during forging. January 30.

2182. J. Sinclair and J. P. Smith. Metallic compounds or alloys. February 20.

2778. F. Trickett and J. Noad. Extraction of gold, silver, and platinum from auriferous and argentiferous materials. January 30.

3179. E. Bowen. See Class II. January 16.

3369. A. Watt. Treatment of zinc ores. February 13.

3410. J. F. Hall. Manufacture and treatment of iron or steel. January 16.

3548. L. Q. Brin. Method and apparatus for making aluminium bronze. January 23.

3549. L. Q. Brin. Process and apparatus for obtaining alloys of aluminium, particularly aluminium bronze. January 30.

3741. C. Appleby.—From Rankin, Brayton, and Co. Ore-concentrating machinery. February 13.

3963. W. Holland, jun. Method and appliances for heating, hardening, and tempering metallic wire. January 16.

3965. T. R. Jordan. Extraction of metals from their ores by amalgamation, and apparatus therefor. January 16.

4014. C. Shannon. Manufacture of armour plates. February 13.

4086. J. C. Ball. Metallic alloys or compounds. January 23.

4281. J. Beasley and A. J. Wood. Lining or fettling for iron and steel furnaces. February 6.

4430. G. J. Atkins. Treatment of metallic ores, and apparatus therefor. January 30.

4842. G. A. Jarvis. Manufacture of sodium or potassium. February 6.

5116. J. Willis and Co. Anti-corrosive steam propeller blades and castings for marine, mining, and other purposes. February 20.

5665. W. Evans. Blast furnaces. February 20.

11,020. C. A. Faure. Producing aluminium chloride. February 20.

11,339. H. Ostermann and A. Prip. A new metallic alloy. January 16.

12,683. D. Hutton. Calcining pyrites and other gold-bearing ores. January 16.

13,117. J. Kleinpeter. Compound castings for armour plates or chilled castings and inset iron armour-plates. January 16.

13,234. L. A. Groth.—From O. Leprevost-Bourgerel and E. Pierron. Extracting tin from tin scrap. February 20.

14,833. A. E. Sarti. Copper amalgamating plates. January 30.

16,671. F. W. Koller and A. Breden. Process and apparatus for zincing metal articles. February 13.

17,068. H. H. Lake.—From O. B. Peck. Separating metals, &c. from molten slag. January 23.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

1888.

18,194. J. L. Roberts and H. L. Brevoort, London. Improvements in galvanic batteries and in the arts. Complete Specification. December 18.

18,589. J. L. Hulser, London. Improvements relating to secondary batteries. December 19.

1889.

1056. T. Pense, Liverpool. Improved electrical storage battery. January 21.

1313. E. M. H. Andreoli, London. Improvements in bleaching paper pulp and vegetable fibres by electrolysis. Complete Specification. January 24.

1401. J. T. Dyer, P. Fish, and R. C. Fish, London. Improved mode of generating electricity by dynamo-electric machines. Complete Specification. January 25.

1418. G. Kruss. See Class X.

1420. F. King, London. Improvements in secondary batteries. January 25.

1535. J. A. Timmis, London. Improvements in the construction and working of dynamos. January 28.

1571. T. B. Saunders, Bradford. Improvements in or appertaining to the process of galvanising iron and steel. January 29.

1673. G. Philippart, London. Improvements in the construction of secondary batteries. January 30.

1683. C. A. Caspersen, London. Method of determining the temper of iron and steel. January 30.

1861. W. J. S. Barber-Starkey, Manchester. Improvements in and connected with galvanic batteries. February 2.

2066. L. Paget, London. Improvements in the manufacture of electrodes for secondary batteries or accumulators. Complete Specification. February 5.

2079. A. H. Norman, London. An improvement in plates for secondary voltaic batteries. February 5.

2151. W. J. Woodward and F. H. Judson, London. Improvements relating to electric batteries. February 6.

2206. T. P. C. Crampton, E. G. Colton, and The Medical and Scientific Apparatus Company, Limited, London. Improvements in the electro-deposition of metals, specially applicable for deposition on fragile articles, or coating, plating, or forming articles of irregular surface. February 7.

2276. E. Guillon.—From M. Sappey, France. Improvements in the construction and arrangement of primary batteries. Complete Specification. February 8.

2297. C. Smith.—From W. L. F. Hellesen, Denmark. Improvements in primary and secondary transportable galvanic dry elements. February 8.

2331. W. H. Dowland and W. Mills, London. An improved apparatus for economically effecting the double decomposition of certain substances by the aid of electricity. February 9.

2407. A. Bernstein, London. Improvements in dynamo-electric machines. Complete Specification. February 11.

2472. W. L. Wise.—From The Gibson Electric Co. of Europe, France. Improvements in secondary batteries, and plates or elements therefor. February 12.

2514. A. Douglass and F. Smith, London. Improvements in the form and manufacture of secondary battery frames and plates. February 13.

2642. G. Forbes, London. Improvements in dynamo-electric machines. February 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

2314. S. L. de Ferranti. Electrical safety-fuses. February 13.
 2316. S. L. de Ferranti. Dynamo-electrical machines and apparatus used therewith. February 13.
 2411. L. Mond and C. Langer. Gas batteries. January 16.
 3556. N. G. Thompson. An electrical regenerative battery. February 13.
 4153. P. King. Means for regulating secondary currents derived from continuous current transformers. February 6.
 4940. T. Parker. Alternating current dynamo-electric machines. January 23.
 5528. H. Hermite, E. J. Paterson, and C. F. Cooper. Voltaic batteries. February 13.
 5723. W. Webster. Production of ethylheate waters by electrolytic action, and apparatus therefor. February 6.
 5790. H. Stenach. Preparation of non-metallic porous bodies for electro-metallurgical deposits. February 20.
 15,252. O. E. Madden and A. F. Mullen. Machines for making battery plates. January 23.
 15,369. P. A. Fichet and A. Nodon. Secondary batteries. February 6.
 17,223. L. Paget. Secondary batteries, and electrodes therefor. February 20.
 17,225. L. Paget. Generation of electricity, and the simultaneous production of zinc chloride and other products. February 20.
 17,349. P. M. Justice.—From E. L. Smith. Electro depositing cells. January 23.

1889.

319. W. P. Kookozey. Apparatus for charging and discharging storage batteries. February 13.
 326. W. P. Kookozey. Preparing solution compounds for galvanic batteries. February 13.
 746. O. Lugo. Secondary batteries. February 20.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

1888.

- 11,266. E. Bentz and M. Schloss, Manchester. Improved method and means of refining vegetable oils. December 14.
 18,454. H. de la Spere, London. The making of a medicated soap. December 18.

1889.

1142. H. Guthrie, Liverpool. Improvements in and connected with the manufacture of "oil cake," and expression of oil from oleaginous seeds or kernels. January 22.
 1430. J. Ascouzh. See Class XVIII. C.
 1501. W. McLay, Charlton. Improvements in lubricants. January 28.
 1610. J. von Froeschauer, London. Improved saponaceous compounds and processes for manufacturing the same. January 29.
 2325. R. Hunt, Liverpool. Improvements in treating crude cotton-seed oil and oils containing resinous matter and free fatty acids to obtain oil, soap, and resinous colouring-matter. February 6.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

7830. J. Taylor. Manufacture of soaps. January 16.
 14,526. W. P. Thompson.—From M. Crawford. Treatment of oil-bearing substances during expression of the oil, and presses for receiving and discharging such substances without intermission. January 16.
 16,328. M. Crawford. Treatment of oil-bearing substances during expression of the oil, and presses for receiving and discharging such substances without intermission. January 23.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

1888.

- 18,645. A. Melville, London. Producing a new black solid writing and copying ink, and a new black and coloured solid non-copying ink for writing and drawing. December 20.

1889.

1282. J. B. Hanney, Glasgow. Improvements in making a white pigment of lead, and in apparatus therefor. January 24.
 1346. J. W. Hall, London. Improvements in and to the manufacture of carbonate of lead or white lead. January 24.
 1434. J. B. Hanney, Glasgow. Improvements in treating or purifying sulphate of lead. January 26.
 1578. R. Stone, London. Improvements in the manufacture of paint and pigments. January 23.
 2026. E. G. Soltmann, London. Improvements in ink and colour slabs. Complete Specification. February 5.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

- 15,971. J. Danby. A cement or paint coating for protecting iron ships and other structures liable to corrosion. January 16.
 17,679. A. J. Boulton.—From W. Kiel. Vulcanised plastic compounds. January 30.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

1888.

- 18,307. J. Hauff, London. A new or improved process for the preservation of extracts and liquids containing tannin and used for tanning purposes, by means of cresol, naphthol, cresotic acids, and their soluble salts, as well as a process for preserving kips, skins, or hides by means of cresol, naphthol, and their carbon, containing acids in suitable solution or mixed with suitable solvents. Complete Specification. December 14.
 18,399. M. P. Halseck, London. An improved extract for use as a ferment, and as leather food or dressing. December 17.
 18,429. W. Barnsdale. An improved process for desiccating blood and other analogous substances. Complete Specification. December 17.

1889.

1345. B. Nicholson and T. Palmer. See Class I.
 1492. J. Palmer, London. Discolouring hemlock, mimosa, divi-divi, and other red tannins. January 25.
 2771. W. Gridley and F. B. Pike, London. Improvements in the manufacture or treatment of gelatinous substances. February 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

1818. G. W. Rhodes. Tanning by electricity. January 16.
 4765. A. H. Hobson. See Class XV.
 7007. C. L. Royer. Treatment of hides for belting. February 13.
 18,307. J. Hauff. See application above. January 30.
 18,429. W. Barnsdale. See application above. January 23.

XV.—AGRICULTURE, MANURES, Etc.

APPLICATIONS.

1888.

1617. F. Parlenkoff, London. An apparatus for obtaining a fertiliser by separating the liquid from the solid parts of excreta sewage, and the like, and by automatically mixing the solid parts with peat or the like. January 29.
 1710. W. Riddough, Bradford. Improvements in the means or method of treating or preparing certain refuse matter to increase its fertilising properties. January 31.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

4765. A. H. Hobson. Treatment of bones and animal refuse for rendering same suitable for fertilising purposes, and for obtaining gelatine, glue, and size. January 30.
 18,906. P. M. Justice.—From W. J. Williams. Manufacturing nitrogenous fertilisers from phosphates of iron and alumina. January 30.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

1888.

18,380, S. C. Whitting and G. Turk, Berlin. Improvements in the method of extracting starch from straw bollings. December 17.

1889.

16,000, G. B. Mee.—From E. C. da Silva, Brazil. Improvements in the extraction of sugar from syrups. January 29.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

245, W. H. Stead. Manufacture and purification of gums. January 16.

4209, A. Chapman. Sugar-cane mills. January 23.

4893, H. V. R. Read. Sugar-cane mills. February 6.

6030, R. Harvey.—From T. S. Cornish. Defecators for saccharine and other liquids. February 13.

6778, H. Kiel and R. Stoltenhoff. Manufacture of starch. February 13.

13,334, J. Grass, G. C. Heilman, and O. Olmce. Manufacture of saccharine liquors for brewing and other purposes. January 16.

1889.

75, O. Lenz. Manufacturing crystallised maltose. February 13.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

1888.

18,286, H. A. Birrell, London. Improvements in the treatment of ground malt for brewing purposes. December 14.

18,422, C. Philippart, London. Improvements in the treatment of alcohols and alcoholic liquors for the purpose of improving their quality. December 17.

18,618, C. M. Pielsticker, London. Improvements in the purification of alcohol. December 20.

1889.

1582, C. R. Bonne, London. Improvements in the preparation of fermentable, especially brewers', worts. January 29.

1912, G. G. Cave and J. H. Howell, Bristol. Improvements in apparatus for promoting circulation and aeration of brewers' wort. February 4.

2110, K. Moller, London. Apparatus, methods, and arrangements adapted for breweries, distilleries, and other installations for charging spaces or chambers with air free from micro-organisms (microbes) and their germs, and preventing air containing the same from penetrating therein and into wort and other substances. February 6.

2291, T. D. Challoner, Newcastle-on-Tyne. The manufacture of liquid yeast. February 8.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

3193, E. Thatcher. Manufacture of brewers' finings, and apparatus therefor. January 16.

3510, E. Maubre. Process and plant for treating cereals and starchy substances for making alcohol and vinegar, &c. February 6.

3574, B. W. Valentin. Improvement in brewing. January 16.

4616, K. Bernreuther and W. Kumpfmüller. Apparatus for ascertaining the degree of maceration of barley when malting. January 23.

13,534, J. Graso and others. See Class XVI.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—CHEMISTRY OF FOODS.

1889.

1201, W. Gerbel, London. Improvements in and relating to the manufacture of milk-powder and effervescent beverages. Complete Specification. January 22.

1423, F. McIntyre, Glasgow. An improved process and means for the preservation of milk. January 25.

1449, E. Pott, London. Improved mode of and means to be used in preserving organic substances. January 26.

B.—SANITARY CHEMISTRY.

1888.

18,568, C. H. Beloe, Liverpool. Improvements in and connected with the purification of sewage and other foul liquids. December 19.

1889.

1144, C. F. Gower, Ipswich. An improved apparatus for extracting the solid suspended matter from sewage or other liquid. January 22.

1628, J. Bradbury, London. Improvements in or relating to the construction of destructor furnaces, and in means for heating the same for burning noxious vapours, gases, refuse, garbage, and other analogous substances. January 30.

2381, B. D. Henley, Bamber Bridge. An improved method of applying gaseous fuel for treating towns' refuse and the fumes therefrom. February 11.

2541, J. Martin, London. A new or improved method of treating sewage and the effluent therefrom. February 13.

2543, G. Forbes, London. Improvements in apparatus for utilising town refuse. February 14.

C.—DISINFECTANTS.

1888.

18,620, J. Ascough, Birmingham. Improved antiseptic washing and cleansing compounds. December 20.

1889.

1430, J. Ascough, Birmingham. A new and improved method of manufacturing glazing, antiseptic, and washing compounds. January 26.

2537, A. J. Shilton, Reading. A new disinfectant and deodoriser. February 13.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—CHEMISTRY OF FOODS.

1888.

3530, Brin's Oxygen Company Limited, and P. B. W. Goble. Carbonated oxygen water. January 23.

5042, J. White. Manufacturing flaked Indian corn. January 30.

12,774, H. H. Lake.—From F. S. Van Choate. Composition and devices for preserving animal and vegetable substances. February 6.

15,364, Sir E. B. Sladen, R. McLeod, and C. H. White. Treating Dangway beans as a substitute for coffee. February 13.

B.—SANITARY CHEMISTRY.

1888.

2561, R. E. Phillips.—From F. S. Harwood. Softening and purifying water. January 23.

2592, R. E. Phillips.—From F. S. Harwood. Disinfecting and purifying sewage. January 23.

4547, T. L. Seaton. Apparatus for separating solid matter from water or other liquids. January 30.

5861, G. W. Bremner. Preparation and combination of ingredients for precipitating and disinfecting sewage. February 13.

C.—DISINFECTANTS.

1888.

5631, J. Johnson. Composition for cleaning and disinfecting culinary and table utensils. February 20.

6407, H. H. Lake.—From C. H. Shaw. Disinfectants. February 20.

18,775, W. B. Giles, A. Shearer, and F. G. A. Roberts. Production of bisulphite and meta-bisulphite of sodium or potassium. February 20.

XIX.—PAPER, PASTEBOARD, ETC.

APPLICATIONS.

1888.

18,658. A. Diana, London. An improved manufacture of paper and cardboard. Complete Specification. December 20.

1889.

1433. R. Hamilton and J. C. Hamilton, Glasgow. Improvements in treating or cleansing paper-making materials and other fibrous materials and fabrics. January 26.

1834. C. Ramsey, London. Improvements in the manufacture and bleaching of wood and other pulps, and apparatus for that purpose. February 1.

2432. D. M. Watson and T. T. M. Lumsden, Glasgow. Improvements in apparatus for the manufacture of paper. February 12.

2792. E. C. de Mejer and T. Greenwood, London. A new and improved method of manufacturing "paper-stucco." Complete Specification. February 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

346. J. R. Thame, Barrels, &c., made from paper or like pulp, and apparatus employed. January 16.

3321. A. Bensinger. Producing indelible designs on celluloid or like compounds. January 16.

4931. J. Turnbull, jun. Apparatus for boiling esparto grass, &c. February 6.

12,682. J. Maclear. See Class V.

17,692. O. Imray.—From J. R. France. Manufacture of celluloid, &c., and apparatus therefor. January 23.

17,876. A. Lundberg. Boilers for treating wood and other fibrous matters with acid solutions. January 16.

18,658. A. Diana. See application above. February 6.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATION.

1888.

18,521. E. Schnauffer and Hupfeld, London. The manufacture of a substitute for musk. December 18.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

1889.

1461. W. J. Wilson, London. Improvements in photographic transparencies. Complete Specification. January 26.

2623. J. Leisk, Lerwick. A new or improved flash lamp for the rapid combustion of magnesium powder to be used for photographic or other purposes. February 14.

2723. F. W. Hart, London. Apparatus for controlling the exposure of photographically-sensitive plates, when using flash-lamps. February 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

4537. J. B. Germeil-Bonnaud. Photographing in colours. February 13.

4874. E. S. Williams. Photographic emulsions. January 16.

XXII.—EXPLOSIVES, MATCHES, ETC.

APPLICATIONS.

1888.

18,362. J. W. Skoglund, London. Improvements in the manufacture of explosive compounds. December 15.

18,663. H. S. Maxim, London. Improvements relating to the manufacture of explosives, and to apparatus therefor. December 20.

1889.

1115. H. M. Chapman, London. Improvements in or relating to the manufacture or treatment of explosives. January 21.

1988. A. V. Newton.—From A. Nobel, France. An improved mode of preparing explosive compounds for use. February 4.

2017. W. R. Barlow, Woolwich. A hydraulic time fuse. February 5.

2678. O. Imray.—From P. C. Fraser, Germany. A process for granulating and glazing gelatinous explosives. February 5.

2346. H. T. Robinson, London. A tool for operating on fuse lighters of the kind known as "Bickford's patent colliery fuse lighters." Complete Specification. February 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

1471. A. V. Newton.—From A. Nobel. Manufacture of explosives. January 16.

3989. C. L. Dressler. Explosive projectiles. February 6.

5624. C. A. McEvoy. Improvements in fuses. February 20.

5961. M. E. Hall. Torpedoes. February 6.

1889.

635. R. W. Heenan. Apparatus for charging cartridges with pulverulent explosive. February 13.

XXIII.—ANALYTICAL CHEMISTRY.

COMPLETE SPECIFICATION ACCEPTED.

1888.

2367. J. Marx. Method and means for separating matters in solution by osmose, dialysis, or diffusion; or by electrolysis, or by a combination of those processes. January 23.

THE JOURNAL OF THE Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 3.—VOL. VIII.]

MARCH 30, 1889.

[Non-Members 30/- per ann.; Members 21/- per Set of Extra or Back Nos.; Single Copies 2/6.

NOTICES.

Notice is hereby given that the Annual General Meeting will be held in London in the month of July next. Full particulars will appear in a subsequent issue.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Post Office Orders in payment of subscriptions should in all instances be made payable at the General Post Office, London.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

LIST OF MEMBERS ELECTED, 22nd MARCH, 1889.

Anderson, Clement W., Mass. Inst. of Technology, Boston, Mass., U.S.A., chemical demonstrator.

Callander, Wm. S., Mill Brow, Appleton, Widnes, alkali works manager.

Chase, Roseoe L., 1336, Spring Garden Street, Philadelphia, Pa., U.S.A., professor of chemistry.

Evans, Reginald E., Beaulieu, Mornington Road, Woodford, Essex, chemical student.

Ford, Jno. S., 11, Abbotsford Park, Edinburgh, chemical demonstrator.

Glaser, Chas., P.O. Box 437, Baltimore, Md., U.S.A., chemist and manufacturer.

Gregory, Wm., Trent Valley Brewery, Lichfield, brewer and chemist.

Heath, Geo. L., Mass. Inst. of Technology, Boston, Mass., U.S.A., chemist's assistant.

Hunt, Fred. J., Bow Bridge Soap Works, Stratford, E., soap maker.

Jarvis, Jno. W., 6, Princess Street, Leicester, headmaster, Newton's School.

Lewis, Arthur E., 3, Upper Fitzwilliam Street, Dublin, analytical chemist.

Lowman, Dr. Oscar, 185, Jefferson Avenue, Detroit, Mich., U.S.A., manufacturing chemist.

Scovell, M. A., Lexington, Kentucky, U.S.A., Director of Agric. Expt. Station.

Shield, Henry, Messrs. Fawcett, Preston, and Co., Ltd., 17, York Street, Liverpool, civil engineer.

Singer, Lematus, c/o J. Carter Bell, Higher Broughton, Manchester, manufacturing chemist.

Smith, George, 60, Whitworth Road, Rochdale, chemist.

Sulman, H., Livingstone, c/o Hopkin and Williams, Waterside, Wandsworth, chemist.

Taylor, Richard H., 21, Marjorie Street, Leicester, manager.

Tothill, Mortimer A. L., Kieboek Square, Cape Town, South Africa, manufacturing chemist.

Turner, Percy R., Tar Works, Rothwell Haigh, near Leeds, manager.

Williams, Outram F. Monier, Bow Foundry, Bow, E., ironfounder.

CHANGES OF ADDRESS.

Carnelley, Prof. T., 1/o Dundee; The University, Aberdeen.

Cunningham, A. Auchie, 1/o Edinburgh; American Sugar Refinery, San Francisco, Cal., U.S.A.

Doolittle, O. S., 1/o Altoona; Philadelphia and Reading Railroad, cor. 7th and Franklin Streets, Reading, Pa., U.S.A.

Dugzan, T. R., 1/o Clapton; Sunnysbank, Vanbrugh Hill, Blackheath, S.E.

Eschellmann, Dr. G., 1/o Northwich; c/o P. Eschellmann, O. 7, No. 8, Mannheim, Germany.

Hall, Edgar, 1/o Mitchell; Chemical Laboratory, The University, Sydney, N.S.W.

Hartley, Jos., 1/o Brook Road; Dalton Chemical Works, Brook Street, West Gorton, Manchester.

James, J. H., 1/o Old Broad Street; 337, Brixton Road, S.W.

Kay, H. A., 1/o 13; 71, Maida Vale, London, N.W.

King, C. M., 1/o Finchley; Helens, North Green, Highgate, N.

Lawrence, Jas., 1/o Toms River; Repanno Chemical Co., Gibbstown, N.J., U.S.A.

McCubbin, W. A., 1/o The Elms; Mill Bank, West Derby, Liverpool.

Metcalf, Wm., 1/o Stanhill House; Aspin House, Oswaldtwistle.

Miller, Geo., 1/o Runcorn; Fern Villa, Bold, Widnes.

Newbury, Prof. S. B., 1/o Cornell University; c/o Munroe and Co., Bankers, Paris.

Orr, Alex.; Journals to 118, Pitt Street, Sydney, New South Wales.

Samuel, W. Cobden, 1/o 203; 337, Norwood Road, West Norwood, S.E.

Smith, J. Tertius, 1/o Braintree; Tyne Vale Chemical Works, Forth Banks, Newcastle-on-Tyne.

Steinhart, Dr. O. J., 1/o Garrett Lane; 15, Bolton Gardens West, South Kensington, S.W.

Tennant, Sir Charles; Journals to St. Rollox, Glasgow.

Terry, Albert, 1/o London; c/o Buckhurst and Buxton, Clarendon Street, South Melbourne, Victoria.

Thomas, H., 1/o Sunderland; 9, Millicent Terrace, Gateshead.

Walsh, P. H.; Journals to Shadyside, Crescent Ridge Avenue, Clifton, Ohio, U.S.A.

Whitehouse, Enoch, 1/o 128; 118, Coventry Road, Birmingham.

Zinkeisen, Wm.; Journals to Krausenstrasse 61 III, Berlin, Germany.

NAMES WRONGLY OMITTED FROM LIST OF MEMBERS.

Rawcliffe, Harold, Gillibrand Hall, Chorley, Lancashire.
Stanning, John, Broadfield, Leyland, Preston.

Death.

Williams, John, 63, Warwick Gardens, Kensington, W. March 2.

London Section.

SESSION 1888-89.

- April 1st.—Dr. Percy F. Frankland. "The Action of Water on Lead."
"Messrs. Cross and Bevan. "Economy of Pure Caustic Soda."
May 6th.—Mr. C. Napier Hake. "Notes on Explosives."
June 3rd.—Messrs. Newlands Bros. "Improvements in Centrifugal Machines."
"Dr. W. S. Squire. "The Purification of Alcohol by means of Hydrocarbon Oils."
July. — Annual General Meeting.

Meeting held Monday, March 4th, 1889.

MR. DAVID HOWARD IN THE CHAIR.

SPECIFIC GRAVITIES OF PARAFFIN WAXES AT DIFFERENT TEMPERATURES.

BY LTJED L. REDWOOD.

As but few data have been published in regard to the specific gravity of paraffin waxes at different

temperatures, it is hoped that the following figures will be of interest and value, especially to manufacturers and those who have to deal with wax in the molten state.

Mr. Alfred H. Allen states* that the specific gravity of paraffin wax at a temperature of 140° F. is 780.5, and at a temperature of 208.4° F., 753; but he omitted to mention what the melting point of the wax was.

The same author, in a paper "On the specific gravity and some other characters of waxes and allied bodies"† shows that a wax of 130° F. melting point has a specific gravity of 909 at 60° F., and 753 at 210.2° F.

In the second edition of his "Commercial Organic Analysis," Vol. II., page 411, Mr. Allen gives the following table showing the specific gravity and melting point of paraffin wax from different sources:—

Origin of Sample of Wax.	Specific Gravity.		Solidifying Point, ° C.
	Solid, at 15.5° C.	Liquid, at 19° C.	
1. Shale oil	78506	77481	14.0
2. Shale oil	78961	77494	17.0
3. Shale oil	79000	77517	22.0
4. Shale oil	79111	77572	58.5
5. American petroleum	79083	77535	53.8
6. Ozokerite	77531	61.5
7. Rangoon tar	78831	77571	49.0

According to Mr. Galletty‡ the specific gravities of Boghead coal waxes, in the solid state, are as follows:—

Specific Gravity.	Melting Point.
823.6	89.6° F.
848.0	102.2
852.0	104.9
903.0	128.0
911.0	128.0
924.3	130.4
924.8	138.2
940.0	170.0

The specific gravities of refined American paraffin waxes as given below were determined, in the molten state, by weighing quantities of one litre, the flask being maintained at the given temperature while being filled, and for some time afterwards, by submersion in a vessel containing a large quantity of water at the required temperature; and, in the solid state, by making mixtures of alcohol and water of such density that the wax would remain suspended at any point in the liquid at which it might be

placed. The specific gravities of the mixtures were then determined by the specific gravity bottle.

Temp.	Specific Gravity of Molten Waxes.						
	F.	M.P.	M.P.	M.P.	M.P.	M.P.	M.P.
	108°	114°	120½°	122½°	122½°	128½°	133½°
160	770.69	771.93	773.91	770.79	770.23	775.73	777.23
155	771.19	773.30	775.31	771.49	771.63	776.53	778.53
150	773.09	774.73	776.57	773.19	772.83	778.03	780.03
145	775.09	776.20	777.77	775.19	774.63	779.73	781.53
140	776.79	777.63	778.47	776.89	776.33	781.33	783.33
135	778.99	779.53	781.47	778.69	778.43	783.03	..
130	780.49	781.13	782.67	780.29	779.73
125	781.99	783.43	784.41
120	783.59	784.73
115	785.29

Specific Gravity of Solid Waxes.					
M.P.	M.P.	M.P.	M.P.	M.P.	M.P.
106	111½°	120½°	122½°	125½°	131
60	875.25	882.30	898.95	901.05	903.50 908.65

These figures show that the variations in specific gravity are not quite regular, and that the rise from 135° to 140° affects the 108°, 120½°, and 122½° waxes much more than any of the other alterations in temperature; while the greatest alteration in the case of the 114° and 122½° waxes is between the temperatures 125° and 130°, and 145° and 150° respectively.

A curious peculiarity of the 122½° and 122¾° waxes will also be noticed, namely, that although they increase in specific gravity in the solid state with the rise in melting point, yet, in the molten condition they are lighter than waxes of a far lower melting point. This peculiarity was first noted in the 122¾° wax, and three separate sets of determinations were made, and as the results agreed exactly, it was thought that it might be a characteristic of one particular batch of wax. Therefore a second sample, but of 122½° melting point, was secured after a lapse of about 10 days, and as it was taken from a freshly cast cake it could have had no connexion with the first sample experimented with. This wax gave very similar results, and therefore it would appear that the peculiarity is a characteristic of, at any rate some, paraffin waxes of this melting point.

DR. F. HURTER IN THE CHAIR.

MODERN THEORIES OF THE SULPHURIC ACID PROCESS.

BY DR. S. HAMBURGER.

THE sulphuric acid process has proved, as regards theories, an inexhaustible mine to chemical philosophers. Chemists of the highest reputation found this process interesting enough to spend years of research over it, and although the literature of the process is already enormous, it appears that the final word has not been spoken. In 1887, Raschig, in order to supply a long-felt want, published a new theory (Annalen, 241, 242—250; this Journal, 1887, 820) which, to say the least, has the merit of originality. On investigating the action of sulphurous acid on nitrous acid, or more especially the action of sulphites on nitrites, he found that sulphurous acid did not reduce nitrous acid, either in an alkaline or in an acid solution. Products of condensation were always formed in the first instance, which, by their splitting up into simple compounds, made it appear as if a reduction had taken place. The formation of sulphuric acid in the vitriol chambers was explained by a series of similar reactions, and the process proper was subdivided into three phases :—

Nitrous acid first combined with sulphurous acid in the presence of water to dihydroxyamine sulphonic acid. The latter reacted with another molecule of nitrous acid to nitric oxide, and sulphuric acid and nitric oxide was finally reoxidised to nitrous acid. The reason for introducing this new intermediary product appeared to be based on the fact that solutions of nitrites and sulphites gave rise to the formation of a basic salt of the dihydroxyamine sulphonic acid. According to Raschig's own admission it would be scarcely possible to prepare this acid in a free state, as it at once reacts with another molecule of nitrous acid. It is not my intention to-night to criticise Raschig's theory, especially as this subject has been very extensively treated (Ber. 21, 67—87; this Journal, 1888, 208) by the

distinguished author of the classical Handbook on the Manufacture of Sulphuric Acid and Alkali. I therefore content myself this evening with laying before you the principal arguments which Professor Lunge, in upholding and extending his own theory, brings forward against that proposed by Raschig. Lunge first of all calls attention to the fact that Raschig, in establishing his new theory, never experimented with nitrous or sulphurous acid in a gaseous state, nor did he make experiments with gases taken from vitriol chambers in actual work. The first equation (a) must be rejected, as, according to Raschig's own admission, dihydroxyamine sulphonic acid can only be formed if aqueous solutions of nitrites and sulphites act upon each other at a certain concentration and at a temperature below freezing point. Such conditions never occur in any part of the vitriol chamber. According to equation (b) the dihydroxyamine sulphonic acid formed would at once react *in statu nascendi* with nitrous acid, giving rise to the formation of nitric oxide. But in order that this reaction may take place, nitrous acid must be present in excess in every part of the chamber, as, in the absence of nitrous acid, the dihydroxyamine sulphonic acid splits up into sulphuric acid, nitrous oxide, and water. It is scarcely probable that the dihydroxyamine sulphonic acid would always find nitrous acid ready at hand, and consequently nitrous oxide should be found in more than moderate quantities in the gases of the vitriol chamber, which is fortunately not the case, as it would be equivalent to a great loss of "nitre," nitrous oxide being, as is well known, a very stable compound. Neither does equation (c) correspond with facts ascertained by actual experiments. Nitric oxide, oxygen in excess, and water produce nitric acid, and, in the absence of water, nitrogen peroxide. Again, if nitric oxide and oxygen combine in contact with sulphuric acid, nitrososulphonic acid is formed. Raschig finds a support of his theory in the fact of having found 0.0028 to 0.0138 per cent. of ammonia in chamber acid, and thinks the latter the final product of his reactions; but it is just as likely for small traces of ammonia being produced more simply by the complete reduction of nitrogen oxides by sulphurous acid. If Raschig asserts that his theory alone accounts for nitrous acid acting on sulphurous acid only in the presence of water, he evidently overlooks the fact that sulphuric acid— SO_3H_2 —and not sulphur trioxide— SO_3 —is formed in the chambers, and that apart from other considerations, the sulphuric acid must not be too concentrated, to avoid the solution of very much nitrous acid, which would thus get temporarily eliminated from the process. Why is it necessary at all to leave out of consideration the gases, admittedly present in the chambers in enormous quantities, and call to assistance compounds which no one has ever seen or suspected, which the author himself proclaims as unable to exist in a free state, and which are made to undergo changes under circumstances which are never likely to occur in vitriol chambers? Raschig's theory is, therefore, not likely to revolutionise our present ideas on the sulphuric acid process, but Lunge adds, the time has now arrived when to modify his own theory to some extent. In 1885 Lunge, in bringing his views before the scientific world, stated that sulphuric acid combined with nitrous acid, oxygen, and a small quantity of water, to nitrososulphonic acid, which hovered as a mist in the atmosphere of the chamber. On meeting with more water, which was also distributed as a mist, the nitrososulphonic acid was split up into sulphuric acid, which fell to the bottom, and nitrous acid, which could act afresh. It was, therefore, the

nitrous acid, and not the nitric oxide, which played the part of oxygen-carrier in the sulphuric acid process, and the reactions were represented by the equation 1 and 2, thus:—

At the same time the admission was made that local circumstances might partly modify and complicate these principal reactions. Lunge and Naef proved, in 1884, that the composition of the nitrous gases in a chamber working under normal conditions was incompatible with the presence of nitrogen peroxide. In the first chamber nitric oxide was also present, later on only nitrous acid could be detected, whereas nitrogen peroxide made its appearance, if the excess of nitrous compounds in the latter part of the chamber system was abnormally large. It might be objected that the existence of nitrous acid in a gaseous state was still doubtful, but this made no difference, as the theory held equally good for nitrous acid as a hydrate— NOOH . As a further objection against the nitrous acid theory, the argument has been brought forward that the analyses of the gases might be equally well interpreted as showing the presence of a mixture of nitric oxide and nitrogen peroxide. But could this objection be upheld? Would it not be curious, if one molecule of nitric oxide were always accompanied by one molecule of nitrous acid, never by more, never by less? The universally admitted fact of the ready oxidation of nitric oxide also spoke against this supposition. Again, in the atmosphere of the chamber, many particles of sulphuric acid and water floated as a mist; the former on meeting with nitrogen peroxide was bound to form nitrososulphonic acid and nitric acid, and still more of the latter would be produced by the reaction of nitric oxide, oxygen and water. The whole amount of nitric acid would be dissolved in the chamber acid, as nitric acid is only slowly reduced by sulphurous acid or nitric oxide. Such quantities of nitric acid in the chamber acid would be readily detected, whereas the chamber acid contained, as a rule, very little nitric acid. If it were now admitted that the yellow-red fumes in a vitriol chamber chiefly consisted of nitrous acid, the sulphuric acid process would apparently also conform to Berzelius' theory, as shown in the equations 1a and 2a.

Lunge can no longer give his adherence to this theory. Firstly, wherever sulphuric acid is formed a large amount of nitric oxide should be found side by side with nitrous acid, whereas the analyses of gases taken from different parts of the chamber system prove that, as a rule, this is not the case. Secondly, nitric oxide and oxygen do not form nitrous acid in the immediate contact with sulphuric acid, and consequently all theories based on the reduction of the nitrous gases to nitric oxide must be rejected. It corresponds far more with facts to adopt the theory based on the formation of nitrososulphonic acid and its subsequent decomposition by steam. In connexion herewith it is important to remember that although sulphuric acid of the concentration of the chamber acid dissolves appreciable quantities of nitrososulphonic acid at common temperatures, the conditions in the vitriol chambers are altogether different. There, particles of the various compounds are intimately mixed in a fine diffusion and at an elevated temperature, which circumstances are all in

favour of the decomposition of the nitrososulphonic acid by steam, which is present everywhere. Indeed, before the general introduction of the Glover tower, nitrous vitriol was subjected to the treatment with steam for the purpose of denitration, which reaction is identically the same. It has been previously mentioned that Lunge and Naef found nitric oxide in the thick white fumes of the first working chamber just behind the Glover tower, and Lunge admits that his theory requires a modification for this part. Here sulphurous acid, nitrous gases, oxygen and water meet in the highest state of concentration, here the highest temperature predominates; it is also here that the reaction proceeds most freely, and the formation of sulphuric acid is most abundant. Under these circumstances it is not unlikely that a portion of the sulphurous acid is directly oxidised to sulphuric acid, thus:—

These reactions account for the presence of nitric oxide, which, no doubt, is afterwards oxidised, not simply by oxygen, but by oxygen in the presence of sulphurous acid and steam, thus:—

It is worth repeating that the gases of the second chamber contain nitrous acid only, and no nitric oxide.

A local excess of steam may oxidise nitric oxide to nitric acid, which, being in a gaseous state at the prevailing temperature, is quickly attacked by sulphurous acid and converted into nitrososulphonic acid according to the equation:—

The oxidation of nitric oxide to nitrogen peroxide cannot here take place, as this reaction would require dry oxygen, which is out of the question in the comparatively steam-laden atmosphere of the chamber. There is still another explanation for the occurrence of nitric oxide in the first part of the chamber. It is quite conceivable that the excess of sulphurous acid, steam, and a high temperature, combine to denitrate nitrososulphonic acid, thus:—

This is indeed the same reaction which goes on immediately before in the Glover tower, where the nitrous vitriol from the Gay-Lussac tower, which is, of course, a solution of nitrososulphonic acid in sulphuric acid, is subjected to similar conditions. To sum up. According to Lunge, the equations 1 and 2 represent the principal reactions of the sulphuric acid process proper. Temporary and local conditions may alter the state of things to some extent, as shown by the equations 3 to 7. Or in other words: the sulphuric acid process is not an alternate reduction and oxidation of nitrous gases, but depends rather on a condensation of nitrous acid (or nitric oxide) with sulphurous acid and oxygen to nitrososulphonic acid, and on a splitting off of the nitrous acid by the action of steam on nitrososulphonic acid.

No theory on the sulphuric acid process can be considered complete or satisfactory that takes no cognisance of the unavoidable loss of "nitre" during the process of manufacture. Whereas the "mechanical" loss will vary in different works with the apparatus in use, the scientist may confine himself to

the explanation of the "chemical" loss. Raschig pleads for his theory that it is the only one which rightly explains this loss. Whereas, theoretically, a certain quantity of nitrous acid should oxidise an infinite amount of sulphurous acid, we find in practice that 1 mol. of nitrous acid is actually consumed for every 75 mols. of sulphurous acid. In other words, of every 75 mols. of nitrous acid introduced into the chamber, one does not return to it in a useful form: in what manner it is lost is not positively known. If the formation of dihydroxyamine sulphonic acid be admitted as an intermediary product of the sulphuric acid process, it may occur that one molecule of this compound on the point of splitting up does not find ready at hand the second molecule of nitrous acid, which is necessary to form nitric oxide. The dihydroxyamine sulphonic acid would then split up to sulphuric acid and nitrous oxide, which latter is lost to the process. To avoid this, care must be taken to have always a large excess of nitrous acid in the chambers, and nothing is better known in the practice of the sulphuric acid maker that the loss of nitre is least under these circumstances. Furthermore, it is conceivable, that dihydroxyamine sulphonic acid sometimes reacts with sulphurous acid instead of with nitrous acid, and is thereby reduced to hydroxyamine disulphonic acid, hydroxylamine, and even ammonia. As previously mentioned, Raschig has proved the existence of minute quantities of ammonia in a crude chamber acid, which contained no nitrous acid. His experience has recently been confirmed by Mr. Hasenlever of the "Rhenania" and Dr. Häussermann of Griessheim, near Frankfurt a M. Lunge's explanation of the "chemical" loss of nitre is based on the formation of nitrous oxide and nitrogen peroxide, and he traces the causes that tend to bring about this undesirable result. The reduction of nitrous acid to nitrous oxide by sulphurous acid can only take place in the presence of much water or a more dilute acid than ever occurs in vitriol chambers. The excess of water in chambers being at best local only, this reaction takes place comparatively rarely. Far more frequent is the occurrence of nitrogen peroxide in the latter part of the chamber system. Its presence is altogether independent of the amount of oxygen present at the same time, but is caused by the excess of nitrous gases being exceptionally large. Under these circumstances the reaction is completed long before the gases leave the last chamber. No mist of sulphuric acid hangs here, nor is there any sulphurous acid left. The nitrous acid no longer finds compounds with which to combine, and is gradually dissociated in the large excess of oxygen and ultimately oxidised to nitrogen peroxide. One portion of the latter reacts with the chamber acid to form nitrososulphonic acid and nitric acid, whereas another portion enters the Gay-Lussac tower, the acid of which is unable to absorb this extra addition of nitrous gases. The process proceeds still more unfavourably if the supply of nitrous gases be insufficient. The formation of sulphuric acid in the last chamber is then very slow, and there is much sulphurous acid left, which, from want of nitrous acid, acts on the nitrososulphonic acid according to the equation—

Plenty of nitric oxide is formed, which, on account of the low temperature prevailing, combines only very tardily with sulphurous acid, despite the large excess of oxygen. The steam may also oxidise nitric oxide to nitric acid, which sinks unredacted into the chamber acid, thus still more depriving the chambers of their nitrous constituents. Another portion of nitric oxide is reduced to nitrous oxide, as there is

little sulphuric acid in the atmosphere compared with the amount of steam. Furthermore, some nitric oxide escapes unaltered into the Gay-Lussac tower, and, although there is oxygen present to oxidise it, still it is very much diluted with nitrogen, and the sulphurous acid also present counteracts oxidation. Under these circumstances it is frequently the case that the gases appear colourless on entering the Gay-Lussac tower, but turn reddish when they leave the tower and pass into the air. All these factors combine to bring about not only a great loss of nitre, but also a bad yield of sulphuric acid, and the loss grows all the more the poorer the chambers become in oxygen-carriers. That is also the cause of the well-known fact that, if the chambers are in this condition, the extra addition of nitre must be greatly in excess of that usually required, in order to bring the chambers back to their normal state of working. It will be seen that Raschig's and Lunge's views are here again at variance, for the former supposes the dihydroxyamine sulphonic acid to split up into sulphuric acid and nitrous oxide, whereas the latter (and Weber before him) maintain that nitrous oxide cannot be formed here, as it could only be produced from nitric oxide where sulphuric acid is rigidly excluded.

Lunge's severe criticism called forth a reply from Raschig (*Annalen*, 248, 123—140) (this *Journal*, 1888, 747), but the impartial observer will probably come to the conclusion that Raschig somewhat shifted his original position, and, in lieu of strictly answering Lunge's objections, preferred an attack on the "*tu quoque*" principle. This attack by Raschig was followed by another article by Lunge (*Ber.* 21, 3223—3240), and as both investigators have given notice to lay down arms, I have, in conclusion, the honour of laying before you the state of affairs between their rival theories. Raschig still upholds his dihydroxyamine sulphonic acid theory, which he calls a modification of Berzelius' theory. He contends that, although there is no probability of the existence of the dihydroxyamine sulphonic acid, his equation (a) need not be wrong on that account. The same may be said of Lunge's nitrososulphonic acid, "the existence of which even in small traces has never been proved in a well-working chamber." His second equation (b) is very valuable, as it shows the reason and the necessity for having nitrous acid everywhere in excess, in order to prevent the formation of nitrous oxide. Neither Berzelius' nor Lunge's theory explains the injury done by a decreased supply of nitre. His third equation (c), which may be also written $2 \text{NO} + \text{O} = \text{N}_2\text{O}_3$, is the same as that first introduced by Berzelius; and as Lunge denies its correctness, Raschig now brings forward experimental evidence in support of this equation, viz., that nitrous acid is certainly formed from nitric oxide and air. In his reply, Lunge claims credit for having been the first to point out the fact that it was nitrous acid exclusively, and no other nitrogen compound, that played the part of oxygen-carrier in the vitriol chamber. From Berzelius' writings it is clear that he was unacquainted with the fact that nitrous acid and nitrogen peroxide are separate compounds. Raschig's theory, therefore, is at best only a modification of Lunge's own. As regards Raschig's statement of the non-existence of nitrososulphonic acid, Lunge adds that every one acquainted with the process knows that both the chamber acids and the drips are daily tested for "nitre"—that is, their percentage of nitrososulphonic acid. To put the latter on the same footing as the dihydroxyamine sulphonic acid betrays a want of knowledge of the simplest facts of the sulphuric acid process. Raschig's statements show that he is

unable to interpret the results of experiments. He always draws a wrong conclusion or quotes experiments which have no connexion with the process going on in the chambers. In trying to prove the oxidation of nitric oxide by air to nitrous acid, he uses an apparatus which is badly arranged and does not allow of a thorough mixing of the gases. If this fault be remedied, nitrogen peroxide is the product of oxidation, as previously asserted by Lunge.

I have now given you a report of the latest investigations on this highly-interesting process. I think most of you will agree with me that Professor Lunge, in his thorough manner, has well nigh exhausted the subject, and unless our present means of investigation are enriched, Lunge's explanation of the reactions of the sulphuric acid process will not be shaken for some time to come. A future generation may strike out in a new direction, and some day Lunge's theory may receive the same pitiless treatment which he dealt out to his opponent.

Raschig's supposition of the dihydroxyamine sulphonic acid as an intermediary product is certainly bold, and we almost feel sorry that his facts are not on a par with his imagination. His explanation of the "chemical" loss of nitre is beautifully simple, but until he gives his supposition a more solid foundation by facts, we are bound to reject it. On the other hand, most of you will feel inclined to agree, on the whole, with Lunge's views; but I, for my part, am not satisfied with his explanation of the loss of nitre during the process. I am not speaking of certain extremes, where the supply of nitre is largely in excess or very deficient. Here Lunge may be right, although I doubt whether, in well-managed works, the amount of nitrous gases in the chambers is ever in so large an excess that nitrogen peroxide is found in large quantities in the last chamber. I may add that this is certainly against my experience. I never found more than traces of nitrogen peroxide in the gases entering the Gay-Lussac tower. You all know that a certain loss of nitre takes place even if the system works extremely well, the greater part of which comes under the head of "chemical" loss, and it is this loss which, in my opinion, has never been explained beyond doubt. I think I am well within the mark if I put down the mechanical loss of nitre at 25 per cent. of the total loss. In addition to it, there is a loss, due to an escape of nitric oxide, which leaves the system unoxidised; this loss is rarely more than 6 per cent. on the total nitre lost. There still remains another source of loss, viz., the reduction of nitrous gases by sulphurous acid in the presence of much water. Eschellmann estimates this reduction at 31.5 per cent. of the total loss, although I think this figure far too high. This liberal estimate at best accounts for two-thirds of the total nitrate used, and it seems only too likely that a reduction of nitrous gases into irrecoverable compounds is taking place during the process, probably in consequence of secondary reactions which are still unknown to us. Until more light is shed on this dark phase, we can scarcely hope to do away with the *bête noire* of the sulphuric acid maker, viz., the loss of nitre.

DISCUSSION.

Dr. HURTER said he was sure that they had all listened with great pleasure to the able account Dr. Hamburger had given them of the two rival theories of Raschig and Lunge. Dr. Raschig, in the course of researches on an entirely different subject, had evolved a theory of the sulphuric acid process based on the formation of dihydroxyamine sulphonic acid. As Dr. Hamburger had

said, in some respects it seemed a pretty theory, since it at first sight appeared to account for the unavoidable passage of nitrogen compounds from the chamber in a form in which they could not be recovered. He (Dr. Hurter) agreed with Lunge that Raschig's body could not be made the basis of a theory of the sulphuric acid process, since it had no existence under the conditions which obtained in the chambers.

Professor Lunge had done more in recent years to throw light upon the reactions which went on in the sulphuric acid chambers than any other investigator, and his theory was based upon the existence in the gaseous state of nitrous anhydride. They were aware that several eminent English chemists had objected to this, and published experiments which seemed to prove that nitrous anhydride did not exist as a gas. But it was sufficient for Lunge's theory if the nitrous anhydride existed as a gas only for a few moments, and his experiments seemed to demonstrate such an existence satisfactorily. Lunge's theory amounted to this: The main reaction was: sulphurous anhydride, oxygen, steam, and nitrous anhydride together formed nitrososulphonic acid, and this was decomposed by steam into sulphuric acid and nitrous anhydride. The secondary reaction was based upon the same combination, but instead of the nitrososulphonic acid being decomposed by steam, it was decomposed by sulphurous anhydride, with formation of sulphuric acid and nitric oxide. If Lunge had made his secondary reaction into his main reaction he would have been more in harmony with the facts, as established in the paper published in conjunction with Dr. Naef. That paper showed that where much sulphuric acid was produced much nitric oxide existed, whilst where little sulphuric acid was made little nitric oxide was found. This seemed to indicate a connexion between the formation of sulphuric acid and nitric oxide of more importance than Lunge had ascribed to it.

He would take the opportunity to call attention to another point of that paper of Lunge and Naef, about which he had been frequently questioned. These gentlemen found, both in works in Switzerland and in England, that the chief amount of sulphuric acid which was made in any chamber of a series was made in the first half of the chamber, and that the second half of the chamber did comparatively little. To many (himself included) this appeared incredible, considering the uniform distribution of all the gases through the chamber, according to Professor Lunge's own facts. The fact was that Lunge and Naef did not measure the amount of sulphuric acid made, they simply ascertained a rapid decrease in the percentage of sulphurous acid. But whether this decrease was due to the formation of sulphuric acid, or to a mere intermixture of the rich gases as they entered with the poorer gases of the chambers, no gas analysis could demonstrate. It would be easy to prove, with a few elementary equations, that it was utterly impossible for gas analysis to distinguish between the two causes for the decrease of sulphurous acid. Consequently, gas analysis could not be appealed to to say how much and where the sulphuric acid was made inside any particular chamber. The difference of percentage at inlet and outlet of a particular chamber could and would tell how much sulphuric acid was made in the particular chamber as a whole, but any further information gas analysis could not give.

Dr. S. HAMBURGER, in replying, said that if Dr. Hurter had seen the article in last week's *Chemische Industrie* by Schertel, he (Dr. Hurter) would not have told them all that he had about

the amount of acid made in different parts of the chamber. Schertel repeated Lunge and Naef's experiments, and completely confirmed them in that the first half of the chamber made the vastly greater portion of the acid, whereas in the latter half very little acid was made. Schertel did not agree with their explanation, and accounted for it in the following manner: In his opinion the nitrososulphonic acid required a great deal of steam to be decomposed. The steam in the chambers was very quickly taken up by the sulphuric acid formed, and the nitrososulphonic acid in the second part of the chamber did not find sufficient steam for decomposition, and consequently there was a scarcity of nitrous acid in that part. Dr. Hurter did not tell them that, when the gases went from the second part of the chamber into the next chamber, the reaction became very energetic and lively again (Dr. HURTER: "Yes, I said it"), and that the reaction became very energetic because of the fresh steam added. Schertel had illustrated this by an experiment which seemed to show that nitrososulphonic acid really required far more steam than was generally supposed. He passed gases as escaping from the first chamber through a long pipe filled with coke into the second chamber. Now, the acid formed in the pipe was only 98° Tw. strong—they would admit that it was far weaker than acid usually made in the chambers. When this pipe was opened a large amount of chamber crystals were found on that side of the coke which faced the current of the gas. Now, it could not be said that they were formed owing to want of water or steam; but it was worth remembering that they were formed in the presence of very much steam. He therefore thought that Schertel was right in ascribing the cause of the second part of the chamber not working as actively and energetically as the first part to want of steam, or, what came to the same thing under the circumstances, to want of nitrous acid.

Dr. HURTER: How did he ascertain that the first part of the chamber did all the work?

Dr. HAMBURGER: By gas analysis.

Dr. HURTER said that, in his opinion, was no use. He would only say that there was a good deal of difference of opinion, but at one time at Messrs. Gaskell, Deacon, and Co., before Glover towers were introduced, the production of sulphuric acid was worked out by means of rain gauges, and if he had happened to think of it he could have brought the books to show them how far the amount calculated from the rain gauges agreed with the amount of salt cake made, and he could assure them it did not differ more than 5 per cent. up or down. On the whole it came out exceedingly fair. Now if any member would use a rain gauge, and would tell him at the next meeting what amount of acid was collected at one end and what amount at the other end of a chamber, he would be glad. They made the experiments for Sir Henry Roscoe, and found very little difference between the two ends of the chamber.

AN IMPROVEMENT IN THE MANUFACTURE OF CHLORATE OF POTASH.

BY M. J. HAMMILL.

I HAVE ventured on reading a short paper on this subject, in the hope that it may be of some interest to members of this Section, and perhaps through the medium of our Journal to others interested in the manufacture of chlorate of potash. All such are well aware that, in the usual method of manufacture, there is a very considerable loss of chlorate in the mother-liquors of the first crystallisation, owing to the fact that it is not possible to crystallise out more, than about, on the average, from 76 to 77 per cent. of the total chlorate contained in the mixed solutions of potassium chlorate and calcium chloride, the remainder being left in the mother-liquor and altogether lost, except in some cases, so far as its chlorine is concerned. It is also a well-known fact that chlorate of potash is less soluble in cold than in warm solutions, and that in practice less chlorate is lost in cold than in warm weather or climates. The consideration of these facts led Mr. Wyld, Mr. Auer, and myself, to experiment on these liquors, by artificial refrigeration, in the hopes of obtaining thereby an increased production of chlorate. Our experiments were carried out at first in the laboratory, and subsequently at the works of the Widnes Alkali Company, Limited, on a manufacturing scale, and the results obtained were sufficiently satisfactory to warrant us in obtaining a patent for the process, no one having previously occupied the ground. These results I will to-night lay briefly before you. But first let me say, that we found, on lowering the temperature of highly concentrated solutions, calcium chloride crystallised out as well as chlorate of potash; but in less concentrated solutions this difficulty is avoided.

Subsequent experiments proved that—

In mother-liquors of—

° Tw.	° F.
82 CaCl ₂ begins to crystallise out at about 36	
80 " " " " " "	30
78 " " " " " "	24
76 " " " " " "	19
75 " " " " " "	11
74 " " " " " "	8
72 " " " " " "	- 10
70 (no calcium down at - 13° F.)	

Having ascertained these facts, we determined that it would be necessary, or at all events advisable, to dilute all solutions to the density at which it would be safe, without risk of crystallising out any calcium chloride, to reduce the temperature to the required point. It will be noticed that liquors of 72° Tw. or under may be safely reduced in temperature to below zero.

We next proceeded to carry the refrigeration of mother-liquors to a practical working trial, and for this purpose hired from Messrs. Siddeley and Co., of Liverpool, an ether refrigerating-machine (Mackay's patent), which they happened to have on stock, and which they were willing to let on hire for the trial. This machine is of a capacity equal to the manufacture of two tons of ice per day, and it was obviously not sufficiently powerful to reduce to zero the total quantity of our mother-liquors resulting from the manufacture of some 10 tons chlorate per week; but it was, we thought, sufficient to prove on a working scale the practicability or otherwise of recovering sufficient chlorate to reasonably repay the outlay for plant and the cost of treating a given amount of liquor.

I need not describe the apparatus in detail, as the principle of these machines is so well understood; and as they have for most purposes been superseded by machines using ammonia, the agent which is now generally allowed, on account of its great power of absorbing heat, owing to its high latent heat and the tension of its vapour, to be the most suitable for refrigerating purposes. The question of refrigeration is quite a subject—and a very interesting subject—of itself; and if any of my hearers or readers are desirous of extending their knowledge or refreshing their memories on the subject of refrigerating methods or machinery, they cannot do better than refer to three papers already read before Sections of this Society. I refer to a paper read by Mr. J. J. Coleman before the members of the Glasgow Section in May 1884; to one read by Mr. T. B. Lightfoot before the London Section in March 1886; and to one by Mr. G. E. Davis, read before the Manchester Section in April 1887. These papers deal somewhat exhaustively with the question of the various methods of refrigeration, and the advantages claimed for each, and I will not attempt to dwell on this side of the subject further than to say that, after full consideration, we have selected, and are now having made, a machine (of a capacity of six tons of ice per day) on the ammonia-absorption principle, manufactured, under the Mackay-Christiansen patent, by Messrs. Siddeley and Co., Limited, of Liverpool. This machine, which is of recent introduction, and but little known at present, commended itself on account of its possessing several distinct advantages to users who require a machine almost constantly at work and requiring very little attention.

I will, however, leave this branch of the subject, and proceed to give a short summary of the methods we have employed, and the results we have obtained on a two months' trial, with the 2-ton (ice-making capacity) ether machine, which, as I have already stated, was not powerful enough for our full work, and especially failed to reduce the temperature of the liquors with sufficient rapidity below about 15° F. To that point we were able, with this machine, to go with tolerable ease, but below that the reduction in temperature was very slow.

It was, of course, necessary to provide a tank or tanks in which to store and refrigerate the liquors, and for convenience in working it is better to provide two tanks, each capable of holding (as time, as well as cold, is required to obtain the best results) one week's liquors after their dilution to the required strength: No. 1 tank to be operated upon whilst No. 2 is being filled up, and No. 2 tank to receive a like attention whilst No. 1 is being emptied and refilled. There is thus no loss of time, which would be inevitable were only one tank employed. These tanks are each provided with a coil of 3-inch cast-iron piping, for the circulation of the brine or calcium chloride, the medium by which the heat is transferred from the liquor in the tanks to the refrigerating apparatus. The coils are arranged as shown in Figures 1, 2, and 3.

Fig. 1.

Fig. 2.

Fig.

The tanks are also lagged with boarding fixed about 3 inches from the iron, and the cavity between filled in with sawdust or other non-conducting material, to prevent heating by radiation. The top of each tank is also covered in with timber. It would obviously be an improvement to introduce some kind of fan or stirrer to keep the liquor in gentle circulation. This may easily be driven by means of a strap and pulley from the engine which drives the brine and ammonia pumps, and this we have provided for in the new and more powerful apparatus which we have ordered; but, so far, we have had nothing of the sort. The man in charge of the apparatus, who has otherwise very little to do, has occasionally stirred up the liquor with a wooden plunger.

When the required temperature is reached the stirring up is stopped for an hour or two, and then the contents of the tank are discharged by a tap (not shown in the tracing) fixed about 9 inches from the bottom. After the liquor is run off to this level the remainder is run out by raising a plug fixed in the bottom of the tank. This latter portion of the liquor, as it is liable to carry away some of the fine crystal, is strained through a canvas strainer, placed conveniently for the purpose.

The refuse liquor may, or may not, as may seem advisable, be run to the still and treated with HCl to set free the chlorine it contains; but it is plain that in this large bulk of liquor, reduced to a very low temperature, we have a very considerable amount of cold-producing power, which might with advantage be employed either to reduce the temperature of the next batch, by being pumped through the coil in the second tank, or in some other way. One very obvious use for it would be to employ it instead of, or supplemental to, the water used for vitriol cooling. Whatever use may be made of its cooling power, it would be no worse, but rather better, for subsequent treatment with HCl, if desired, in the still.

When all the liquor is run off the men go into the tank (the coils being far enough apart to admit of their free movement therein), and brush the crystal off the pipes and the bottom of the tank through a sluice valve into lead-lined barrows, and take it away to be dried in the centrifugal machine. As the crystal is in a very fine state of division, more than the ordinary quantity of it passes through the wire of the centrifugal machine, and it is advisable that all that escapes from the machine should be collected and sent back to the boiling-down pans: waste from this source is thus prevented. The dried crystal—samples of which I have here for inspection—has an average composition, as follows:—

	Recovered Crystal.	Ordinary First Crystal.
	Per Cent.	
Chlorate of Potash.....	86.40	85.16
Chloride.....	2.37	1.73
Chloride of calc. um.....	0.89	3.16
Moisture.....	7.80	8.96
Insoluble matter.....	2.00	0.60
	99.46	99.61

From this it will be seen that the recovered crystal is quite in a fit state to be made into finished

chlorate with no more than once redissolving. I have here samples of finished chlorate, made entirely from crystal recovered by refrigeration, which have been treated quite in the ordinary way with once redissolving in water. The sample contains 99.98 per cent. KClO_3 , and in appearance will be allowed to be fully equal to anything made in the ordinary way. The exceptionally fine crystals, also shown, are selected specimens made from the recovered crystal, and they show, I think, that as fine crystal in point of size, as well as purity, can be made from this source as from any other.

Before directing your attention to the all-important point, as to the amount of chlorate which is recoverable, by refrigeration, from ordinary mother-liquors, I may mention that there is a further advantage to be gained by adopting this method in the possible reduction of the number of vessels employed for the first crystallisation. It is, I believe, the usual custom to allow all liquors to stand for a period of from 10 to 14 days. Now, as the Table No. 1 shows, the chlorate left in solution is reduced to very reasonable limits within seven days, and if all liquors are to be ultimately reduced in temperature to zero or below, there seems to be no reason why any batch should be allowed to stand beyond the time taken in cooling down to atmospheric temperature; a period which in most cases will not exceed from three to four days. Such an arrangement would set free a large number of vessels, and the room they occupy.

I may also mention, before going further, that we have made some experiments on the solubility of KClO_3 in solutions of MgCl_2 at abnormally low temperatures.

We prepared three samples:—

	° Tw.	Grms.	Grms.
No. 1.	52 containing 335 MgCl_2 and 18 KClO_3 per litre.		
No. 2.	54½ "	312 "	12 "
No. 3.	54½ "	366 "	13 "

After being reduced in temperature:—

	° F.	Grms.
No. 1 at 12	was found to contain 12 KClO_3 per litre.	
No. 2 at 10	" "	6.75 "
No. 3 at 30	" "	8.2 "

showing an average reduction by 37.3 per cent. of the chlorate in solution.

The sample No. 3 was found at 30° F. to be depositing crystals of MgCl_2 , which indicates that in magnesium, no less than in calcium chloride liquors, there is a point of concentration, *below* which it is advisable to have the liquors intended for refrigeration.

And now we come to the question of the quantity of chlorate which is recoverable from ordinary mother-liquors by refrigeration. Table No. 2 will throw some light on this interesting point; it is a return of what we have actually effected in practice during a two months' trial with the 2-ton ether machine.

It will be noted that in batch No. 2 we were dealing with a liquor of too high concentration; the consequence was, at about 18° F. we found a large quantity of calcium chloride had been deposited. The refrigeration was therefore stopped, and the mixed crystal, after drying in the centrifugal machine, was found to contain 32.4 per cent. CaCl₂ and 32.5 per cent. KClO₃. This crystal was covered with a few inches of cold water, and after standing some time, was again dried with the result shown. It will be seen from the table that we have treated seven batches of mother-liquor with an average reduction of 11.28 grms. KClO₃ per litre, and that at

an average temperature of 9.7° F. And we have very little doubt that when we have more powerful apparatus at work, and are able to reduce the whole of our liquors to zero, or better still to *minus* 10° F., that we shall not leave more than, say 10 grms. KClO₃ per litre, in any mother-liquors we turn out. It may be said that this reduction to 10 grms. per litre is a figure not likely to be realised, but if you will refer to Table No. 3, which shows the downward progression of grms. chlorate per litre in the ratio of the reduction of temperature, I think you will agree that we have substantial grounds for our expectations.

It may, I think, be taken as a general average that there are 340 cubic feet of mother-liquor to every ton of finished chlorate made, and that this liquor will contain on an average throughout the year not less than 25 grms. KClO_3 per litre, 340 cubic feet \times 25 oz. = 4 cwt. 3 qr. 5 lb. chlorate, which means a loss of 23.97 per cent. With 13.54 grms. per litre left in the liquors (the average figure we have reached with a reduction of temperature to 10° F. only) the loss is reduced to 12.88 per cent., and the production raised to 87.12 per cent. But if only 10 grms. KClO_3 per litre be left in the liquors (on a reduction in temperature to, say, -10° F.) then we should have a loss of only 9.46 per cent., and a production of 90.54 per cent. as against 76.03, the ordinary average—an increased production of 14.5 per cent., or, say, one ton in seven.

It may be said that for commercial reasons it is not desirable to increase the production of chlorate by one-seventh, but there can at all events be no question that it is very desirable, and especially so at the present time, to decrease by this amount the quantity of salt cake, hydrochloric acid, manganese, lime, potassium chloride, fuel, and labour required per ton of chlorate made. And this reduction by one-seventh of the cost of production, less the cost of packages and of carrying on the operation of refrigeration, will be the measure of the value of our process.

Chlorate makers will all know the cost of producing that article. It will vary, no doubt, somewhat according to circumstances. We will therefore consider only the cost of carrying on the refrigerating process necessary to obtain this increased production of one-seventh. In the first place, there is the cost of the apparatus, and that will of course depend upon the quantity of mother-liquor to be dealt with. It may be useful to say that we calculate, to deal with the liquors resulting from a weekly manufacture, not including the amount recovered, of—

10 tons chlorate	refrigerating	76 tons ice per day is
8	apparatus equal to	required.
5	"	5
"	"	4
"	"	"

We must add to the cost of the refrigerating apparatus that of the two tanks and circulating coils, &c.; but it would perhaps convey a better idea of the possible cost of the plant, to say that we calculate that an expenditure of 1,200*l.* is ample to provide for the treatment of liquors resulting from a manufacture of 10 tons chlorate per week, and for half that quantity it need not be much more than half that sum.

The labour necessary to carry on the refrigerating process can in no case amount to more than the wages of two men to attend to the apparatus; but in most cases no *extra* labour whatever will be required, as some of the existing staff (the octagon men, for instance) can give the amount of attention necessary to keep the apparatus working smoothly.

To assume, for the sake of example, that it is desired to deal with the liquors resulting from a manufacture of 10 tons chlorate per week, not including the amount recovered, the cost of refrigeration would be somewhat as follows:—

	£	s.	d.
Interest and depreciation on 1,200 <i>l.</i> at 10 per cent. for 50 working weeks	2	8	0
Loss of ammonia, say 10 <i>l.</i> per annum do., do.	0	4	0
Fuel, at $\frac{1}{2}$ cwt. per hour = 6 tons 6 cwt. per week, at 5 <i>s.</i>	1	11	6
Oil and stores, say, per week	0	1	6
Wages. None <i>extra</i> required.			
Water for cooling, 650 galls. per hour, available for other purposes.			
Total cost per week	4	5	0

Thus we have an increased production of one-seventh—on 10 tons equal to 1 ton 8 cwt. 2 qrs., for an expenditure of 4*l.* 5*s.*—a result which we think will compare very favourably with those claimed for more ambitious processes which have been tried to reach the same end, namely, to reduce the loss of chlorate of potash inherent to its manufacture, on account of its solubility at ordinary temperatures.

DISCUSSION.

Dr. HURTER said it was one of the most practical papers they had had that session. It dealt with a new process, and a very important one evidently, because anyone could see that the increase of one-seventh in the production of chlorate was not an unimportant item. He must congratulate Mr. Hammill and his friends upon having hit upon the simple expedient of refrigerating to get so largely an increased production as one-seventh of chlorate, and he congratulated him also upon the interesting paper he had written on the subject and on the practical results as shown in the tables.

Mr. H. BRUNNER said that Mr. Hammill mentioned that he found it advisable to dilute the mother-liquors before subjecting them to the refrigeration process. Now it struck him that there was a very considerable disadvantage in doing that, because he must use a considerable amount of water which had to be cooled down, and the cooling was an expensive business. Mr. Hammill had told them that if the mother-liquors were refrigerated without the addition of water, chloride of calcium would crystallise out. Well, of course, that one would expect; but he supposed it did not follow that the chlorate of potash would not crystallise out also; and if the two crystallised out together, one would naturally suppose that the more concentrated the solution the larger the quantity of chlorate of potash which would crystallise out. If the two crystallised out together and were allowed afterwards to come back to the ordinary temperature, there would be sufficient water present to redissolve all the calcium chloride which might have crystallised out, and there would be no difficulty in effecting the separation of the two. It would simply mean passing the mixture of calcium chloride solution and chlorate of potash crystals through the centrifugal.

Mr. E. CAREY had understood Mr. Hammill to say that on a production of 10 tons per week of chlorate the cost of his process was 4*l.* 5*s.*; that, he presumed, was the cost of refrigeration. Would Mr. Hammill put that into terms of ice and say the number of tons of water at 32° F. converted into ice at 32° F. for this 4*l.* 5*s.*

Dr. J. CAMPBELL BROWN asked whether Mr. Hammill knew whether the specific heat of the solution was much lower than that of water.

Mr. HAMMILL, in reply, assured Mr. Brunner that the increase in the bulk of the liquors, owing to the dilution with water, was very slight. The degrees Twaddle between which calcium chloride came out and when it did not, varied very slightly. At 72° Tw. they did not get any CaCl_2 down at 10° F., whilst at 74° Tw. it came down at 8° F. The dilution necessary to bring the liquors to a safe point was therefore inconsiderable. If the liquors were not diluted there would be a pasty mass of mixed crystal, which would be more difficult to deal with, and cost more trouble and more expenditure to separate, than diluting the liquors in the first instance would give rise to.

In reply to Mr. Carey, of course they would understand they did not make ice, and had none of the extensive appliances necessary for making and storing solid ice, nor the expense of handling it. What he spoke of was refrigerating power equal to the manufacture of 6 tons of ice per day, and Mr. Carey would be quite correct in saying that the figures mentioned, 4*l.* 5*s.*, represented the cost of refrigerating power equal to 36 tons of ice per week. The fuel, $\frac{3}{4}$ cwt. per hour, was not a large item, and as to the loss of ammonia, the makers of the refrigerating apparatus guaranteed the loss to be not more than 5*l.* per annum, but he had thought it safe to put it down at 10*l.* The total cost came to about 2*s.* 4*d.* per ton of ice-producing power. He might mention that he had heard of a contract being entered into by some makers of refrigerating machinery to erect an ice plant and work it for 12 months. They to be paid 2*s.* 4*d.* per ton of ice produced in the tanks, of course not to be charged with the handling, storing, or distribution of it. He was also informed that the contractors would make a profit at this figure. In thanking them for the kind reception given to his paper he must acknowledge that he had the co-operation all through of Mr. Wylde and Mr. Auer; only one of them could read a paper, but they had all been associated in the investigations.

DR. BAILEY IN THE CHAIR.

RESINOUS CONSTITUENTS OF CAOUTCHOUC.

BY HUBERT L. TERRY, A.I.C.

It has been shown by Spiller (*Jour. Chem. Soc.* 27, iii, 44) that decayed india-rubber, or that which has undergone atmospheric oxidation, consists in part of a hard resin containing 27 per cent. of oxygen. Burghardt (this Journal, 1883, 189) stated that Spiller's resin was an acid, was soluble in alcohol, ether, and benzene, and formed, with alkalis, soaps soluble in cold water. He also stated that another resinous body was produced by the oxidation of india-rubber, which had different properties from the above, being insoluble in alcohol, ether, and benzene, and not being saponified by alkalis. Burghardt further said that sound india-rubber, which might contain up to 3 per cent. of the soluble resin, never contained any of the insoluble.

Having had the opportunity of examining chemically both the raw and manufactured rubber, it seemed of interest to add a contribution to the meagre literature at present published on this subject.

I prefer to limit the word caoutchouc to the hydrocarbon $C_{10}H_{16}$, and to use the word india-rubber, or, more shortly, rubber, for all other purposes. It is well known that the various qualities of rubber which are imported to England have a very different commercial value according to the proportion of sand, water, resin, albumen, &c. contained in them.

The information already published concerning those impurities is of a very general character, and no detailed analyses are given.

To the statement that the difference in value of the rubber is due to the impurities contained, it must be added that it does not seem to have been proved whether there is any molecular difference in the hydrocarbon as obtained from the various species of trees; the firm elastic Para might, if mixed with the foreign matter that accompanies the African or Asiatic varieties, lose its best properties.

The processes of washing which the raw rubber goes through serve to free it from most of the impurities excepting the resins, which, of course, are unacted upon by water. It is to these latter that I wish to draw special attention, the object of this paper being to show the points of resemblance and difference between those resins naturally occurring in the sound rubber and those which are formed at a later period by the oxidation of the hydrocarbon.

Generally speaking, the value of raw rubber is inversely as the amount of resin contained, while in manufactured rubber the amount of resin has been taken as a direct indication of the degree of oxidation. It will be seen that the latter test would be erroneous if any quantity of natural resin was contained in the rubber under examination. The resin extracted should, therefore, be examined further to ascertain its origin.

The results of resin estimations made at various times have been collated, and are given in Table I., together with the melting points and physical nature.

TABLE I.

Name of Rubber.	Per Cent. of Resin.	M.P., °C.	Remarks.

" flake....	41.2	20	" "

The numbers were obtained after the rubber had gone through the processes of washing already referred to.

It is only in this way that comparative results can be given suitable to the purposes of this paper.

The resin was obtained by exhausting the rubber, cut into fragments, with 90 per cent. alcohol in a Soxhlet's tube. After distilling off the alcohol the residue was well washed with water to remove some nitrogenous and saccharine matters. By employing a porcelain Niekels' filter in connexion with the vacuum pump, the tedious operations of washing and filtering were much facilitated. The aqueous solution on evaporation to dryness often showed glucose by the Fehling reaction. This might be due to decomposition of natural glucosides from the tree, or the reduction might be caused by some benzoine compound. The latter is very probable, especially as tests of the resins seem to show that they belong to the group of aromatic gum resins. The above sweet substance has quite different properties from the methyl-ethers of inoside described by Girard (Compt. Rend. lxxiii., 426) as occurring in certain varieties of caoutchouc.

The melting point determinations are not of much value, as it is clear that the resins are mixtures, and also absorb oxygen from the air. The numbers, however, though not absolute, are of comparative value. The method adopted was to place the resin in a test tube containing a thermometer, insert the tube in a beaker of water, and heat on the sand-bath, the point at which the resin adhered to the glass being taken as the melting point. The method of "Curves of cooling" was of no value except as indicating that the substances were not uniform.

It will be seen by those acquainted with the subject that the value of the rubber is approximately inversely as the per cent. of resin as mentioned previously. All the varieties of rubber examined contained resins mostly peculiar to themselves. These have not yet all been examined in detail, and the further remarks on their chemistry will, in this paper, be limited to the Pará, Rio Janeiro, and African ball products. The very name of resin is a warning against assigning formulæ, yet, though no theoretical interest attaches, the ultimate analysis is of importance as showing the difference of constitution from the oxidation products already mentioned.

Combustion of Rio Resin with CuO .

The resin was washed with potassium carbonate dried at 100°C ., and kept over H_2SO_4 .

Combustions of African ball resin gave oxygen 13 to 14 per cent., showing great difference from Spiller's resin.

Properties of Resins.

Solubility.—All the natural resins examined are soluble in alcohol, ether, chloroform, benzene, and CS_2 .

Pará.—This is a mixture of soft resin with phenolic compounds from wood tar, produced by the smoking process. This resin is characteristic of Pará rubber.

African Ball.—By the potash fusion test, Hlasiwetz and Barth (Annalen, 139, 225), it yields a phenol ether, and gives off an aromatic vapour. It is insoluble in alkaline carbonates. Fuming nitric acid yields other resins, and ultimately oxalic acid.

Soluble in petroleum ether.

Rio.—By potash fusion yields a slight aromatic vapour, but no phenol.

Alkalis and nitric acid same action as the last.

Only slightly soluble in petroleum ether.

Table II. gives the potash and bromine absorptions per cent.

No solid Br compounds were obtained from the natural resins, but the oxidised caoutchouc gave a body insoluble in ether; this has not yet been analysed. The Br absorption was determined by dissolving the resin in chloroform, adding excess of standard bromine in chloroform (strength 1 cc = .05 grms. Br) and allowing to stand for a few minutes. Potassium iodide was now added, and the solution titrated with thiosulphate after the well-known manner.

For the potash absorptions the resin was boiled with excess of seminormal alcoholic potash and titrated back with seminormal HCl and phenolphthaleïn.

Resin.	KHO Absorption.	Br Absorption.
(Spiller's) resin A	20.08	129
Pará.....	18.59	46
African Ball.....	6.27	89
Rio.....	6.04	26

Having considered the natural resins, I now turn to those produced by the atmospheric oxidation of caoutchouc. These have been already mentioned at the commencement of this paper, and may be called, for distinction, resin A (Spiller's), and resin B (Burgardt). The latter is said to be insoluble in absolute alcohol, though I find a resin with its properties in the alcoholic extract from decayed rubber. It appears to undergo change on keeping, and to vary in its action towards alkalis. It is probable that both of them undergo molecular change under certain conditions. They were separated by means of benzene, and samples of both are now on the table. The above, when mixed with natural resins, as may occur in an alcoholic extract from decayed rubber, may be separated by the following method.

Separation of Resins.

The alcoholic extract of the rubber is evaporated to dryness on the water-bath. A small quantity, .2 grms., is weighed out into a tared test tube, and boiled with benzene. Resin B melts and sticks to the glass, when the solution of the other resins can be poured off. After passing a current of air through the test tube, it is reweighed.

The benzene solution is evaporated to dryness, and heated with potassium carbonate solution which saponifies resin A. Filter through a tared filter, dry and weigh. This gives the natural resin. The resin A, minus the per cent. of sulphur, is best obtained by difference. Sulphur is always present

to some extent in the alcoholic extract from vulcanised rubber; it is easily recognised under the microscope by the rhombic crystals, polarising strongly. It is estimated by oxidation with fuming nitric acid, and allowed for in the calculation.

Example.—A mixture was made of 127 grms. Rio resin, and 171 grms. mixed oxidised caoutchouc resins = 42.6 per cent. Rio resin, 57.4 per cent. A + B resins:—

The subject of decay has been gone into by Hoffmann (*Jour. Chem. Soc.* 1861, 87), and W. A. Miller (*ibid.* 1865, 273) for gutta percha, and more recently by Burghardt (*this Journal*, 1883, 119) and W. Thomson (*ibid.* 1885, 710) for india-rubber. Reference to these papers shows that further proof of the injurious action of oxygen is not required.

I hope, in a future paper, to go into the subject of decay, especially with respect to the various vulcanising processes. The subject is one of some complexity, and conclusions cannot be drawn from isolated analyses; much depends on the treatment the rubber receives, and the conditions of its manufacture. It is evident that the process of assimilating oxygen is a constant one, commencing with its extraction from the tree. Dr. Burghardt has given an analysis in which the carbon, hydrogen, and sulphur make up the sum total; this is, I think, not of frequent occurrence, as oxygen is rarely absent. Dr. Gladstone informed me that, when engaged in his recent research (Gladstone and Hibbert, *Jour. Chem. Soc.* 1888, 679), his great difficulty was to get the hydrocarbon free from oxygen. By precipitating the chloroform solution with alcohol, and drying in a vacuum, the caoutchouc obtained generally contained 3 per cent.

Divers and Kawakita (*ibid.* *ccciv.*, 270) found the caoutchouc obtained from "*Ilex aquifolium*" to contain 2 per cent. of oxygen. These analyses confirm my own results made on raw and masticated Pará.

It is important when investigating these resins to be sure that the *terminus a quo* of the rubber was really a tree, because, in these progressive days, it is possible to meet with rubber which never has had any botanical connexion. I am at present extending Dr. Gladstone's researches on Pará caoutchouc to the African and Asiatic imports.

In conclusion, I must express my thanks to Messrs. Chas. Macintosh and Co. for facilitating the production of this paper.

ESTIMATION OF IRON IN WATER.

BY J. CARTER BELL, A.R.S.M., F.I.C., ETC.

Is a water case in which I was engaged some months since, this question was asked in court: How much iron may a river water contain, and yet be fit for bleaching purposes? An eminent water analyst was in the witness box; he made reply, from 0.1 to 0.2 of a grain to the gallon. This gentleman could have had no experience in bleaching, or he could not have given such an absurd statement. I think I may safely assert that no river water in the kingdom contains so large a quantity of iron as 0.1 of a grain

to the gallon, of course chalybeate springs excepted, and even if these were to run into a river the iron would soon be deposited. The case in which I was engaged was where a firm of bleachers brought an action against a firm of dyers who were six miles up the river. The complaint was that waste dye waters containing iron were thrown into the river, and this polluted water found its way into the complainant's reservoir. At that time I obtained many samples of water from various points of the six miles course, and I analysed several hundred samples of water for iron, and in no one case when the sample was taken about a mile from the offending works could I find an amount of iron equal to 0.1 of a grain to the gallon, and I need not say that the quantity found at the point named would be infinitesimally small by the time it arrived at the complainant's works. The judge seemed greatly impressed with one of the complainant's experts, who gravely informed his Lordship that when the iron was once put into the water, the iron, being indestructible, must of necessity come down to the complainant's works and do the damage which was alleged. It would have been fairer on the part of this witness if he had said that the iron in the water at complainant's works was no more than is found in the Thames, Severn, or any other great river in England, which may vary from one part in five millions to one part in seven or ten millions.

The process I adopted for the estimation of the iron was a very considerable modification of Dr. Carnelley's method, of which he read an account before the Manchester Literary and Philosophical Society in 1874. This colorimetric method is not new for a paper was published in 1871 by H. Rheineck in Dingler's *Polytechnisches Journal* on the estimation of iron in liquids used in dye works.

Seventy cc. of the water were evaporated to dryness in a platinum dish, the residue gently ignited to burn off organic matter. One cc. of pure nitric acid were then added, and allowed to flow over all the residue. The nitric acid was evaporated off on the water-bath. The residue was again moistened, this time with 1 cc. of a 10 per cent. solution of hydrochloric acid, about 5 or 10 cc. of distilled water added, warmed on a water-bath, and the solution filtered into a 50 cc. Nessler tube. The filtrate was made up to 50 cc. This 50 cc. must be poured into another 50 cc. tube containing 1 cc. of freshly made ferrocyanide solution. To this mixture 1 cc. dilute nitric acid was added; this is then compared with a tube containing a known weight of iron.

Standard solution of iron: 1 cc. = .001 of iron.

This is made by taking the purest and finest iron wire, dissolving in nitrohydrochloric acid, evaporating to dryness, taking up with a slightly acid solution of hydrochloric acid. I consider this preferable, as it is more stable than the sulphate of iron and ammonium.

Standard ferrocyanide: 1 part of salt in 25 parts of water.

Standard nitric acid: 50 cc. of strong acid made up to litre.

Standard hydrochloric: 100 cc. of strong acid made up to litre.

It is absolutely necessary that a blank experiment be made with pure distilled water; if a slight blue colour is obtained, a correction can then be made in estimating the iron in the sample of water.

MR. T. W. STUART IN THE CHAIR.

ON GAS-TESTING AND SAMPLING APPARATUS.

BY J. E. STEAD.

SEVERAL times during the last ten years I have made communications to the Iron and Steel Institute, describing various forms of gas-testing apparatus which I have designed for the purpose of examining the gases from blast and other furnaces, and it is my intention this evening to exhibit and describe the apparatus, which has, however, undergone considerable improvement since attention was first drawn to it.

I. Sampling of Gases.

When it is required to sample gas which is constantly changing in composition, such as is the gas from all furnaces or fires using coal or coke as fuel, it is impossible to obtain any average representative portion of the gas by simply drawing off a single pipette full by means of the old-fashioned pump.

The old system used to be to draw several of such samples at different times over a considerable period, and to test each sample, and then average the results obtained. It was necessary, therefore, to make several analyses in order to obtain an average result.

Mons. Gruner describes a better method, by which a large vessel, filled with mercury, is used to collect the sample. The vessel has a tap both at the top and bottom. The upper end is placed, by means of a tube, into communication with the gas it is desired to sample, and a receiver is placed below. When both taps are opened the mercury flows from the vessel, and is replaced by the gas which is thus drawn in. By regulating the outward flow of the mercury, regular portions of gas may be drawn in, over any length of time, and a fair average sample obtained in one bottle.

The sampler which I have designed is based on the same principle, but it is so arranged as not only to take the sample, but also to take the place of the old form of gas pipette. It is in most compact and portable form, and may be enclosed in a suitable case. It can be placed on the ground, or hung up on the side of a gas-flue or wall to draw in the gas, and left to itself after once starting it.

With the help of a diagram the working of the apparatus will be readily understood.

Fig. 1.

H is the gas receiver.

A is the mercury reservoir.

E and D at the upper end in communication with the top of the receiver are gas passages.

F and C are mercury passages.

In taking a sample of gas the whole arrangement is hung on the side of the flue from which the sample is to be drawn.

The mercury reservoir is raised and placed on the shelf B, and the taps C and D are opened. The air in the vessel H, thus driven out, is completely replaced by mercury.

The tap C is now closed, and the reservoir lowered. The tube communicating with the flue is then connected to the limb E, and, after opening the taps E and D, the gas is sucked right through the upper tubes, by which means any air that may be present is drawn out of the tube connexions.

As soon as this is done, the tap D is closed, and the opening at the top of the reservoir A having been placed under the tap F, the latter is opened, and the mercury allowed to flow into A at any desired speed. As the quantity of gas flowing into the collector is the same as the quantity of mercury flowing out, it will be clear that the former can be regulated to the greatest exactness by measuring the mercury as it flows out in a graduated tube, noting the time required to pass 10 cc. mercury, and comparing this with the whole contents of the vessel H, and the period over which the sample is to be taken.

If it is desired to keep the sample for some time before testing, the passages in the upper tubes must be filled with mercury by inverting the apparatus and opening the taps for a moment.

The sample, when complete, can be taken to the laboratory, the reservoir A placed upon B, and the tap C opened.

When the gas-testing apparatus is ready to receive it, the tap D is opened, and, after a certain amount of the gas has thoroughly expelled the air from the tube D, it is connected directly to the apparatus, and the necessary quantity is drawn off for analysis.

In examining blast-furnace flues, it is always found that, when taking an average sample, the amount of dust is so great that the ends of the small tubes inserted are frequently choked up. It has been my practice, therefore, to cover the end of the inserted tube with asbestos, and the asbestos with copper-wire gauze. By this means, although the gauze gets covered with dust, the gas passage is always maintained.

In the apparatus most recently made by Messrs. Mawson and Swan, the vessel H is firmly secured on the stand, and both the stands B and G are made into trays, to prevent any loss of mercury.

As in all other glass gas apparatus, it is imperative that the taps be removed when not in use.

In sampling blast-furnace gases, it may fairly be assumed that the gas at any point across the section of a flue is approximately the same at any moment; in other words, that there is no disposition for carbonic acid, or any constituent, to concentrate itself near the walls or centre of the gas passage. This being the case, a small tube may be inserted at any distance into the flue, with the certainty of obtaining an average sample.

With some other gases it is very different. In the gases from boiler fires, for instance, at one time the fire-grate will be bare on one side or other, and a brisk current of air will be passing along that side, and will refuse to perfectly mix with the other gases before it passes to the chimney. If, then, the sample was drawn from one side of such a flue, it is clear that an erroneous sample would be obtained. In taking samples in cases of this class, a long slit tube should be used, which should be placed right across the central part of the flue. If it is practicable, two such tubes at right angles would be preferable, the gas being drawn off at the centre.

It is really a very difficult matter to obtain fair samples of waste gases in some cases, especially when they are below the atmospheric pressure.

Sometimes, at the chimney end of the boiler, there are fixed loosely-fitting draw-dampers, and large quantities of air are drawn into the flue, or near to the end of the boiler.

In such a case all these openings should be plastered up with clay before attempting to take a sample.

In other cases, owing to bad masonry or other causes, air finds its way in, in spite of all precautions.

In sampling the gases from portable engines, the smoke-box door should be carefully luted up, so as to avoid any entrance of air, and the sample should be drawn off near the funnel, through a slit tube, bent into a circle, so as to surround the exhaust-pipe.

In all cases the intelligence of the operator must be used, so that the tubes may be in such a position as to receive an average sample.

II. Gas-Testing Apparatus.

The original form consists, as you will see from the diagram annexed, of a eudiometer tube, the upper end of which is joined at right angles to the capillary tube A E, furnished with taps, one on each side of the eudiometer. This part, when detached, has the appearance of the letter T. Platinum wires are fixed in the upper part of it, for the ignition, by the electric spark, of the combustible gases. The lower end is drawn out to a small diameter, and it communicates directly, by means of an india-rubber connexion, with the mercury reservoir C, which

slides perpendicularly between two grooved parallel guides, and, by means of the T-piece I, with the

Fig. 2.

tube G, which is of the same diameter as the eudiometer tube, and placed parallel with it at the right. The latter communicates with the air by the small tube H. The tube E communicates directly with the single absorption tube F.

The tube A on the left of the eudiometer is used to receive the sample of gas, and also the oxygen or hydrogen which may be required for the analysis. In front of the apparatus is a sliding spirit-level, to assist in adjusting the level of the mercury in the tubes D and G, and also for reading off the volume of the gas.

Both the eudiometer tube D and the parallel tube G are surrounded by a vessel containing water, for maintaining a constant temperature of the gas enclosed.

A small bichromate battery of two or three cells, a Ruhmkorff's coil, and a few yards of connecting wire, complete the apparatus.

Before using the apparatus it is necessary to calibrate the eudiometer tube. This is effected by first filling it completely with mercury, and after closing the lower india-rubber connecting tube with a screw-clip, and the T-piece I being withdrawn, successive portions of 10 measures of mercury are run out into a glass vessel and weighed until the lowest division in the eudiometer is reached, and from the weight obtained a capacity or calibration table is constructed.

Second Form.

This form differs from the first in one particular only, viz., there are three absorption tubes connected to the eudiometer instead of only one. Each tube has an independent tap, so that each can be put into communication with the eudiometer without interfering with the other. The connexions are made with india-rubber tubing.

Third Form.

This apparatus (Fig. 3) which is an important departure from all existing gas-testing devices, is designed so as to rapidly and accurately test gases of the most complex kind. The laboratory vessels,

Fig. 3.

as will be seen from the diagrams, are increased to six in number, and are capable of being revolved on a suitable turntable, and by a special very simple device connected to the eudiometer tube, so that

six different reagents may successively be brought into communication with the gas under examination. Instead of the steel face-plates and screw clamps used by Dr. Frankland, or india-rubber connexions, the eudiometer tube and each of the absorption tubes is furnished with a solid, perfectly flat, piece of plate glass perforated in the centre. These plates are firmly cemented to the tubes by a suitable cement.

The face of each plate is slightly smeared with olive or other oil, and when it is desired to connect two tubes two face-plates are brought in conjunction and are pressed together by means of the little spring clamp illustrated in Fig. 4.

Fig. 4.

The new connector can be readily used with the first apparatus described, and with all gas-testing apparatus made.

MR. E. C. C. STANFORD IN THE CHAIR.

ON FLAME.

BY P. J. ROWAN.

THE subject of flame possesses considerable interest from a technical point of view, because the questions connected with its nature and propagation enter into our understanding of several problems which are of first-rate importance to practical applications of science.

The nature of flame and the temperature which results from its existence bear directly upon our application of fuel and on the intensity of the heat which we produce by combustion. The velocity of ignition is a matter which in several ways is closely connected with the safe working of collieries; and recent research has shown us that the principles of gas-engine practice embrace considerations alike of the nature, temperature, and propagation of flame.

In the following remarks the author aims merely at setting forth some of the general principles of the subject, without making any specific application of them to the important problems indicated.

Nature of Flame.—What is flame? Dr. Mills has remarked that a flame may be regarded as volatile matter undergoing chemical change at a visibly red heat; and Dr. Percy, with more minuteness, says: "Ordinary flame is gas or vapour of which the surface, in contact with atmospheric air, is burning with the emission of light."

These definitions leave little to be desired, as they properly direct attention to *visibility* rather than to temperature, and to the fact that the presence of combustible *gas* or *vapour* is a necessary condition to the existence of flame. We may have a solid, such as iron, magnesium, or carbon,* burning in oxygen or air, at a high temperature, with brilliant incandescence, or glowing, but without flame, whilst, on the other hand, the flame of boric methide shows that flame may exist without a high temperature.

Flames are usually regarded as simple or compound, according to the number of products which result from them. Those which are ordinarily used in the arts and manufactures are compound flames.

From the foregoing definition of flame, it will be readily understood that all flames are more or less hollow in structure. In the centre is a space occupied by unconsumed gases; surrounding that is the luminous portion of the flame; and outside of all is the non-luminous part, or "mantle," as it is called. The unconsumed inflammable gases can be collected from the centre of the flame and afterwards ignited, and the mantle can be rendered more visible (according to Bloxam†) by burning sodium near the flame, when the mantle will acquire a strong yellow tinge.

In a blow-pipe flame, the same construction is observed, the flame, however, being diminished in

size and luminosity; but by mixing air with gas before ignition, the three portions of a flame are reduced to two, with a considerable reduction in the luminosity of the flame. The combustion becomes complete at an earlier period, and the luminous cone has the same character as the mantle in the former case.

Temperature and Propagation of Flame.—Some interesting observations made by Deville* on the flame of carbonic oxide burned with oxygen show the chemical composition of the gases at various parts of the flame. He found that when a mixture of carbonic oxide and oxygen in the combining proportions (2 vols. CO to 1 vol. O) was allowed to issue, under a slight pressure, from a jet having an area of 5 square mm., a flame of 70 to 100 mm. high was formed, consisting of an inner and an outer cone. The outer cone, in which combustion takes place, was deep blue at the base and yellowish or nearly colourless towards the apex. In the inner cone, which was only 10 mm. high, no combustion took place, because the rapidity of displacement of the particles of gas was there superior to the very slow rate of propagation of heat in the mixture.

To collect the gases from the different parts of the flame, a silver tube, pierced with a small aperture, was placed across it in the part to be examined, and the gases were aspirated by passing a rapid stream of water through the tube. They were thus quickly cooled, and, passing along the tube together with the water, were collected, by means of a bent delivery tube, in jars over water.

The following table gives the results of the various observations, the first column giving the positions of the silver tube above the orifice from which the gases issued, the second column the temperatures approximately at these points, and the last division of the table the composition of the gas at the different portions of the flame:—

Height above Orifice.	Corresponding Temperatures.	Composition of the Gas.		
		CO.	O.	CO ₂ .
Min.				
67	Melting heat of silver, and above.....	0.2	21.3	78.5
54	Melting heat of gold.....	6.2	28.1	65.7
41	Commencing white heat of platinum.....	10.0	20.0	70.0
35	White heat of platinum.....	17.3	24.8	57.9
28	Strong white heat of platinum.....	19.4	26.5	54.1
18	Intense white heat of platinum.....	29.0	25.1	45.9
15	Incipient fusion of platinum.....	49.0	32.9	27.1
12	Melting point of platinum.....	47.0	36.0	17.0
(1) 10	Sparkling of the melted platinum.....	55.3	35.3	9.4
(2) 10	Still higher temperature.....	55.1	36.5	8.4
(3) 0	61.4	33.3	2.3

(1) A little above the apex of the inner cone.

(2) Somewhat below the apex of the inner cone.

(3) Original mixture.

These numbers show that the highest temperature is at the apex of the inner cone, or a little below it; that the temperature gradually diminishes towards the apex of the flame; and that the quantity of

* This is true of single pieces of carbon—a mass of carbon burning in air or oxygen generally shows a lambent blue flame on the surface, which is due to the burning of carbonic oxide, CO, formed by the reduction of the carbonic anhydride, CO₂, in its passage through the glowing carbon.

† "Chemistry," edition 1867, p. 95.

* "Bull. Soc. Chim." [2], v. 111: also Watts, "Dict. of Chemistry."

carbonic anhydride increases in the same proportion from the apex of the inner cone, where, at most, two-thirds of the carbonic oxide and oxygen enter into combination, to the vertex of the flame itself, where carbonic oxide can no longer be detected. At the apex and edges of the inner cone the carbonic oxide and oxygen unite almost instantaneously, but only partially, on account of the very high temperature there existing.* Bunsen also carefully investigated this subject, and introduced† some modifications of the views held previously. Watts (Dict. of Chem., i. 860, Affinity) has summarised this matter as follows:—When a combustible gas mixed with oxygen is set on fire, a rise of temperature takes place, which, supposing the combustion to be perfect, may be calculated from the heat of combustion of the gases and the specific heat of the products. If, on the other hand, the combustion is imperfect, the temperature may still be calculated with the aid of Mariotte's and Gay-Lussac's laws, provided the pressure exerted by the gaseous mixture when ex-

ploded in a closed vessel be known. This pressure has been determined by Bunsen for mixtures of hydrogen and carbonic oxide with oxygen, or with oxygen and nitrogen together, by means of a eudiometer having a loaded safety valve. From this and the observed temperature of combustion, the quantity of the combustible gas (carbonic oxide or hydrogen) which has been burnt at the moment when the flame attains its maximum temperature, and thence also the quantity which at this temperature has lost its power of combining, may be calculated.

The following table contains the results of Bunsen's experiments arranged according to the maxima of temperature (t' — t) which the several gaseous mixtures, calculated for volumes at 0° C., attain by combustion in a closed vessel. Columns I. and II. give the mixtures of gases used; $\frac{P}{P_0}$ = the pressure produced in atmospheres by explosion; t = the calculated temperatures; and k = the calculated proportion of combination.

No.	Mixtures of Gases.		$\frac{P}{P_0}$	t .	k .	Mean.	Deviation from Mean.
	I.	II.	III.	IV.	V.		
1	$\frac{2}{3}$ vol. CO + $\frac{1}{3}$ vol. O.....		10.78	3,172	0.351	0.3316	+ 0.0194

5	$\frac{1}{3}$ " CO + $\frac{1}{3}$ " O + 0.1079 vol. O.....		9.05	2,558	0.314	0.5021	— 0.0176
6	$\frac{1}{3}$ " CO + $\frac{1}{3}$ " O + 0.6857 " CO.....		8.89	2,471	0.469		— 0.0121
7	$\frac{1}{2}$ " CO + $\frac{1}{2}$ " O + 0.8854 " O.....		8.44	2,325	0.478		— 0.0241
8	$\frac{1}{2}$ " CO + $\frac{1}{2}$ " O + 1.0861 " O.....		7.86	2,117	0.490		— 0.0121
9	$\frac{1}{2}$ " CO + $\frac{1}{2}$ " O + 1.2563 " N.....		7.73	2,084	0.515	0.5021	+ 0.0129
10	$\frac{1}{2}$ " H + $\frac{1}{2}$ " O + 1.2509 " N.....		7.49	2,024	0.547		+ 0.0449
11	$\frac{1}{2}$ " CO + $\frac{1}{2}$ " O + 1.2563 " N.....		7.35	1,909	0.470		— 0.0321
12	$\frac{1}{2}$ " CO + $\frac{1}{2}$ " O + 1.7145 " O.....		6.67	1,723	0.520		+ 0.0179
13	$\frac{1}{2}$ " CO + $\frac{1}{2}$ " O + 2.1559 vols. O.....		5.83	1,469	0.512	0.527	+ 0.0099
14	$\frac{1}{2}$ " CO + $\frac{1}{2}$ " O + 3.1629 " CO.....		4.79	1,146	0.527		+ 0.0249

These numbers, in Bunsen's view, show that, in a mixture of carbonic oxide or hydrogen with the exact proportion of oxygen required for combustion, and unmixed with any diluent gas, only one-third of the carbonic oxide or hydrogen is burnt at the maximum temperature, whilst the other two-thirds, by being raised to the high temperatures of 2,558° to 3,033°, have lost the power of combining; moreover, that, when one volume of the same mixture is diluted with 0.686 to 3.163 volumes of any gas that does not burn with it, and the temperature of the flame is successively reduced thereby from 2,471 to 1,146°, then, at all temperatures within these, exactly half of the carbonic oxide or hydrogen is burnt, the other half having lost the power of combining.

From this it has been inferred that the combustion of gases takes place in a manner different from that which had been previously supposed. When a mixture of two volumes of carbonic oxide with one

volume of oxygen is set on fire, and its temperature thereby raised from 0° to 3,033° C., two-thirds of the carbonic oxide remains in an unburnt, and for the time incombustible, state. The temperature is then lowered by radiation and conduction from 3,033° to 2,558° without any combustion of the carbonic oxide, but when the temperature falls somewhat lower, combustion recommences, restoring the heat lost by radiation and conduction, and raising the temperature again to 2,558° but not above that point. The gradual fall of temperature from 3,033° is followed by a continuance of the temperature 2,558° till exactly half the carbonic oxide is burnt, whereupon a third phase sets in, during which, again, no combustion takes place until the inflamed gaseous mixture has cooled down to at least 1,146°. As however, the gaseous mixture, after cooling, consists almost wholly of carbonic anhydride, these alternate phases of constant and decreasing temperature must be repeated below 1,146° until the last portion of the gas is burnt. This discontinuous combustion of a uniform mixture of a combustible gas with oxygen is referred by Bunsen to a law of combination established by him.

* See also Thorpe on the Theory of the Bunsen Lamp, "Jour. Chem. Soc.," 1877, i., p. 627, for Blochmann's investigations, or "Annalen Chem. Pharm.," vol. cxlviii., p. 295.

† "Phil. Mag.," vol. xxxiv., p. 489, and "Gasometry," by R. Bunsen.

These facts, as observed by Bunsen, are of great importance in connexion with the inflammation of gases, although it is probable, as Berthelot has indicated, that Bunsen's temperatures are too high in consequence of his not having considered the contraction of volume due to combination.

Berthelot* announced that the combustion temperatures in Bunsen's experiments may be anything between the limits shown in the following numbers, keeping the same numerical order as in the foregoing table:—

No.	t_1	t_2	No.	t_1	t_2
1	4,140	2,612	8	2,280	1,875
2	3,960	2,537	9	2,203	1,838
3	3,809	2,419	10	2,126	1,715
4	3,718	2,389	11	2,083	1,734
5	3,066	2,198	12	1,875	1,518
6	2,760	2,151	13	1,505	1,319
7	2,537	2,031	14	1,150	1,031

A number of experiments on this subject have been made since Berthelot's criticism appeared, but the conclusions arrived at are contradictory. All, however, agree in observing a great absorption of heat at high temperatures, which is thought to be due either to a change in the specific heat of gases or to dissociation. Messrs. Berthelot and Vieille† and Mallard and Le Chatelier‡ have advanced and supported the former view, while the latter has been advocated by Mr. Dugald Clerk§ and Professor Rücker, of Leeds. It is probable that both causes operate to produce the phenomena which have been observed.

The rate of ignition of gaseous mixtures is also a point of considerable importance. Sir H. Davy|| propounded a theory of this action, but it does not seem to be entirely supported by more recent investigations.

Bunsen found that the velocity of the propagation of combustion in a pure detonating mixture of hydrogen and oxygen was 34 metres per second, and in a maximum explosive mixture of carbonic oxide and oxygen it was less than 1 metre per second. When the explosive gases are gradually diluted with a gas that does not take part in the combustion, the rate is lowered, and it can be brought down thus until the progress of combustion is made visible to the eye.

Bunsen's method of determining these velocities is thus described by Dugald Clerk (*loc. cit.*):—The explosive mixture was allowed to burn from a fine orifice of known diameter, and the rate of the current of the gaseous mixture was carefully regulated by diminishing the pressure to the point at which flame passed back through the orifice and ignited the gases below it. This passing back of the flame occurs when the velocity with which the gaseous mixture issues from the orifice is inappreciably less than the velocity with which the inflammation of the upper layers of

burning gas is propagated to the lower and unignited layers.

Professor Mallard,* of the Ecole des Mines, made a series of observations by this method on the rate of the propagation of combustion in mixtures of coal-gas and air, and of marsh-gas and air. In the latter mixtures, the maximum rapidity of inflammation was found to be about 0.56 metre, or rather more than half a yard, per second. This velocity was attained with a mixture of 1 vol. marsh-gas and 8½ vols. air. When the proportion of air was increased to 12 vols. or diminished to 5.9 vols., the mixture was neither explosive nor inflammable.† Professor Thorpe remarks on this that it is worthy of note that the proportion of air corresponding with the maximum rate of inflammation is less than that which contains oxygen sufficient for the complete combustion of the marsh-gas. This, however, is what the observations by Bunsen and others, previously quoted, would lead us to expect.

The maximum rapidity of inflammation in mixtures of coal-gas and air was attained with a mixture of 5 vols. of air and 1 vol. of coal-gas, and was 1.02 metre, or rather more than 1 yard, per second. One volume of coal-gas with 6½ vols. of air gave a rate of 0.285 metre, or 11 inches, per second. The rate was very rapidly diminished by an excess of either constituent; a mixture containing more than 8 vols. and less than 3½ vols. of air to 1 of coal-gas was found to be unflammable in the way described.‡

Dugald Clerk has pointed out that these are the rates of ignition at constant pressure, and that in a closed space the conditions of inflammation are quite different in consequence of the expansion of the ignited portion and mechanical disturbance of the remaining part of the gaseous mixture. Experiments are needed to determine the rate of ignition for constant volume. Some remarkable results are given by this author, which were obtained by so arranging the plan of ignition that a small volume of gases was first ignited, which expanded and projected a flame through a passage into the mass of an inflammable mixture, thus adding to the rate of ignition the mechanical disturbance produced by the entering flame. He succeeded by this means in producing maximum pressure (or maximum ignition) in $\frac{1}{100}$ th part of a second in a space containing 200 cubic inches of gas. By firing a mixture with varying amounts of mechanical disturbance, almost any time of ignition could be obtained between $\frac{1}{100}$ th and $\frac{1}{10}$ th of a second. It did not matter whether the mixture used was rich or weak in gas; the rich mixture could be fired slowly, and the weak one rapidly, just as was required. He found that the rate of ignition of the strongest possible mixture is so slow that the time of attaining complete inflammation depends on the amount of mechanical disturbance permitted.

Mr. Lewis T. Wright has recorded§ some interesting observations on the velocity of the propagation of flame, and has announced that, when flame travels at a greater velocity than 4½ feet per second, it will pass through the gauze used in safety lamps. He also found that a flame of low velocity in a confined space may become so much agitated by an increase in its own oscillations as to cause the introduction of a very rapid rate of ignition in the remaining portions of the gaseous mixture. He

remarks that "a definite explosive mixture may have a velocity of propagation of flame, when it is undergoing explosion of the first order, as low as $1\frac{1}{2}$ foot per second; but when it becomes sufficiently agitated to give an explosion of the second order, the rate of propagation of flame is several thousand feet per second."

The following table shows the results of experiments with various mixtures of gases, giving the rate at which an explosion of the first order (that is, a slow ignition) travels with each mixture in a glass tube 13 feet long and 0.75 inch diameter:—

Mixtures.		Lineal Velocity of Efflux of Mixture.	Rate at which Explosion of First Order travels in Tube.	Total Velocity of Propagation of Flame.
Gas.	Air.	Feet per Second.	Feet per Second.	Feet per Second.
Per Cent. 10.3	Per Cent. 89.7	1.21	1.1	2.31
12.2	87.8	1.24	2.0	3.24
15.0	85.0	1.28	3.0	4.28
17.7	82.3	1.32	4.8	6.12
19.6	80.4	1.35	3.0	4.35
21.2	78.8	1.38	2.4	3.78
22.1	77.9	1.39	1.3	2.69
23.0	77.0	1.41	Stationary.	..

Wright also found that, whenever an explosion is produced inside a safety lamp having ordinary gauze the flame was projected through the gauze, and could ignite gas at a considerable distance from the lamp. By employing stiff wires for the woof and lighter wires for the warp, he produced a "basket-work" gauze having small tortuous openings and a relatively large weight of metal, which did not allow flame from an explosion to pass through.

Luminosity of Flames.—According to the commonly received theory of the causes of luminosity in flames (first propounded by Sir H. Davy*), the presence of solid particles suspended in the flame (or in immediate contact with the burning gas) is essential to its luminosity.

There is no doubt that the introduction of solid particles in a fine state of division into a flame of feeble luminosity will impart to it a considerable degree of brilliancy by the incandescence of the solid particles, or perhaps in some cases by reflection of the light from their many surfaces. No sound conclusion, however, as to the luminosity of flames in general can be drawn from such an analogy as is afforded by the result of such an experiment, because Tyndall has shown that the same result is produced when the solid introduced is one that does not burn. The presence of solid particles, according to the common idea, in luminous flames is only assumed, not proved. It is usual, however, to refer to the black deposit which is formed upon a glass rod or similar body, when it is held in the flame of a candle or of hydrocarbon gas, as a proof that such flames contain solid particles. This, however, is not a conclusive proof, for Dr. Frankland† has pointed out that this deposit is not pure carbon, but is a hydro-

carbon compound. To this Dr. Percy* objects that it is fixed, not volatile, whatever its composition may be; but the objection seems to be irrelevant, because it refers to the substance as deposited, and we do not know that such a substance existed in the flame. The introduction of the cold surface of the glass rod not only condenses some vaporous hydrocarbon, but doubtless also causes decomposition of some of the many hydrocarbons which make their appearance in the gradual resolution of carbonaceous matter. As, therefore, we do not know in what combination this substance producing the black deposit existed while it was originally in the burning gas, it cannot properly be asserted that it was "fixed, not volatile."

The phenomena of many luminous flames are explained by various writers, with more or less ingenuity, on the hypothesis of solid particles, but the experiments and observations of Dr. Frankland† have shown that that hypothesis is not wholly satisfactory, because luminous effects have been produced where it could not account for them, such, for example, as the luminosity of the flame of hydrogen burning in oxygen under pressure; and secondly, because in many of the brightest flames the temperature is such that fuliginous matter‡ could not exist in them. In many cases, it might seem, therefore, to be a more satisfactory explanation, that the luminosity of flames depends on the existence of a comparatively high temperature, and on the presence of gases or vapours of considerable density.§

Soret|| made, in 1874, some experiments which were intended to refute the opinion previously given by Hirn adverse to Davy's theory of solid particles. These experiments consisted in projecting, by means of lenses, the image of the sun on to the surface of several hydrocarbon flames, and examining the degree of polarisation of the reflected light by the use of a Nicol's prism. As the light was observed by the eye, it was necessary to interpose several plates of cobalt-coloured glass, and the sunlight was distinguishable from the light of the flame merely by means of a trace of blue which was ascribed to it as distinct from the purple colour yielded by the flame light.

Soret obtained similar results, though in varying degree, with sunlight when reflected from lampblack, from non-incandescient smoke, from smoky carbon flames, and from the flames of candles and hydrocarbon gas having different degrees of carburization. When, however, the flame, even of highly-carburetted gas, burned in an atmosphere of abundant oxygen, the blue trace and the polarisation effect were invisible. In fact, his best results were obtained in proportion to the decrease of luminosity. On this account Soret was not warranted in concluding, as he did, that his results support Davy's theory, because they failed just when it was important that they should not fail, namely, when the luminosity of the flames was largely increased. If we accept these experiments as showing that sunlight was reflected from finely-divided particles in these flames, they also indicate that the luminosity of these flames was not only *not due* to the presence of these solid particles, but that, on the contrary, it was *diminished*

by them, as they disappeared from the brighter flame.

More recently Burch* has to some extent repeated Soret's experiments, making use, however, of the spectroscopic in the examination of the light from the flame, and thus being better able to distinguish between it and the reflected sunlight. He found that the reflected sunlight showed all the Fraunhofer lines, and that, on using the Nicol's prism, it was polarised at right angles to the line of incidence; and he compared this result with that obtained from the reflection from finely-divided particles of shellac as precipitated by and suspended in water.

The observed effects being the same, he was perhaps justified in concluding that in the flames which he examined, the sunlight was reflected from finely-divided solid particles; although in the present state of this branch of the science of optics, it would be foolish to consider this matter *proved*. Finely-divided solid matter suspended in a viscous fluid, and rushing through a flame, represent very different physical conditions, and it is extremely improbable that we can safely reason from results afforded by one phenomenon to those of the other. The flame itself, by reason of the intense vibrations which constitute its existence, may behave towards sunlight in a manner very different from that of a transparent and almost quiescent liquid.

At any rate, Burch's results are far from proving that the *luminosity* of these flames was in any way dependent upon the presence of solid particles, except in so far (as Soret's experiments teach) as they may have acted in diminishing the degree of luminosity. The mere fact of the *presence* of solid particles, supposing that to be established, does not prove anything regarding any relation between them and luminosity. This is a distinct subject for proof.

On the other hand, the effect of high temperature is seen in the greater brightness of the flames of sulphur, phosphorus, and, indeed, all substances when burnt in pure oxygen, as compared with the result of their combustion in air. Direct evidence of the effect of high temperature is also afforded by the combustion of phosphorus in chlorine, for, whilst at ordinary temperatures only a feeble light is produced by this combustion (although the product PCl_3 has considerable density), strongly heated phosphorus vapour burns in hot chlorine with a dazzling white light.

A comparison of the relative densities of gases and vapours shows that the brightest flames in general are those which contain the densest vapours.

Relative Densities of some Gases and Vapours.

Hydrogen	1
Water	9
Hydrochloric acid	18½
Arsenious chloride	91
Metallic arsenic	150
Arsenious oxide	198
Air	14·5
Oxygen	16
Carbon dioxide	22
Sulphur dioxide	32
Phosphoric oxide	71 or 142
Chlorine	35·5
Mercury	209

Hydrogen burning in chlorine produces a vapour more than twice as heavy as that resulting from its combustion in oxygen, and accordingly the light produced in the former case is stronger than in the latter. Carbon and sulphur burning in oxygen

produce vapours of still greater density (viz., CO_2 and SO_2), and their combustion gives a still brighter light. Phosphorus, also, which has a very dense vapour, and yields, in burning, a product of great vapour density, burns in oxygen with a brilliancy almost blinding.

The luminosity of a flame is increased by compressing around it the surrounding gaseous atmosphere, and it is diminished by rarefying it. Thus, mixtures of hydrogen and carbonic oxide with oxygen emit but little light when they are burnt or exploded in free air, but exhibit intense luminosity when exploded in closed vessels so as to prevent expansion of the gases at the moment of combustion.

Frankland experimented with jets of hydrogen and carbonic oxide burning in oxygen under a pressure which he gradually increased to twenty atmospheres, and obtained brilliant luminous effects, including bright and continuous spectra. Even the faint flame of alcohol, as in an ordinary spirit lamp, becomes highly luminous under the receiver of a condensing pump, when the pressure of air is increased to 120 inches of mercury.

We are indebted to Frankland* also for the observation that the diminution in illuminating power is directly proportional to the diminution in pressure; and, as applied to ordinary domestic gas-burners, this means that, as the barometer falls, the light from them diminishes at the rate of 5·1 per cent. for every inch of fall. According to Dr. Letheby,† “in London the difference in the value of the light when the barometer is 31, as compared with what it is at 28, is fully 25 per cent.”

The flame of arsenic burning in oxygen may also be rendered quite feeble by rarefying the oxygen; and, at high altitudes, flames exhibit the effects of rarefied air. Tyndall and Frankland‡ made observations on the combustion of stearin candles at the summit of Mount Blanc and at Chamouni, and found a considerable decrease in luminosity at the high elevation, although the rate of combustion of the candles remained the same in both places. The energy of combustion was therefore unaltered, although the flame in one case had a higher temperature than in the other, resulting from the increased density of the gaseous atmosphere. Percy shows (vol. “Fuel,” p. 159) that this conclusion should be drawn even from the theory propounded by Tyndall in explanation of the diminished luminosity which he observed on Mount Blanc. Tyndall's theory was, that the decrease in luminosity was mainly due to the greater mobility of the air. From this Percy reasons, “Now, if increased mobility of the air be caused by rarefaction, the opposite should result from compression, in which case the movement of the particles would become sluggish, intermixture of the air and flame-producing gas would be less rapid, and the diffusion of the gaseous products of combustion in the surrounding air would be retarded, with consequent increase of temperature.”

Frankland's conclusions have also been confirmed by some experiments by Professor V. Wartha§ on the influence of pressure on flames.

Obituary.

JOHN WILLIAMS, F.I.C., F.C.S.

A VICE-PRESIDENT OF THE SOCIETY OF CHEMICAL INDUSTRY.

It is with great regret that the death on Sunday, March 3rd, of Mr. John Williams, is herewith recorded, and to this record we may fittingly, as well as truly, add that there are few men whose lives pass away from among us, to whom the tributes of respect for their knowledge and attainments as well as of love and esteem for their personal qualities and character, are at once so largely and so equally due.

Mr. Williams was born in London on March 9th, 1824, and so his death, which took place after but a short illness, ensued within a few days of his 65th birthday. He was the son of Mr. John Williams, sometime Secretary of the Royal Astronomical Society and other learned Societies. As a youth he entered the service of Mr. Thos. Morson, whose assistant he was for some years, and indeed until he became the partner of Mr. W. King Hopkin. In the well-known firm of Hopkin and Williams he continued his labours for nearly 40 years. John Williams was for 17 years a member of the Council of the Pharmaceutical Society of Great Britain, for three years of which he acted as Treasurer, and during three years more he filled the office of President of that Society. In June 1887, fearing that failing health would debar him from what he considered the proper fulfilment of his duties as a member of the Council of that Society, he resigned the post, and this resignation was shortly afterwards followed by his retirement from active business life. He has been officially connected with the Society of Chemical Industry from the very first, and was most regular in his attendance at the Council meetings of that Society. No member of the Society more thoroughly enjoyed the Annual Meetings, or entered, so far as his strength and the increasing infirmities of age would permit, more enthusiastically into the festivities and excursions of that season, than Mr. John Williams. During the last three years Mr. Williams has held the honourable position of a Vice-President of the Society, and it need scarcely be added that the duties of that position have received his most assiduous attention.

Besides being a pharmacist and a manufacturer, Mr. Williams was a sound chemist, and as a consequence of this, the name of his firm became especially associated with the supply of fine chemicals. To this sound knowledge of practical chemistry, his numerous published papers bear ample testimony. The principal of these it may be interesting to enumerate, with the dates of their publication. In 1872, "Note on Guaiacol" and "Guaranine." 1874, "Note on the Administration of Phosphorus." 1874 and 1875, "Notes on the Preservation of Hydrocyanic Acid." 1875, "Note on Salicylate of Methyl." 1876, "Salicylate and Sulphosalicylate of Sodium;" also "Note on some Reactions of the Glycerol of Nitrate of

Bismuth." 1877, "Nitrite of Ethyl." 1878, "Note on Salicylic Acid;" also "Preliminary Note on Aceto-Nitrate of Iron as a Medicinal Agent." 1884, "Note on certain Anhydrous Essential Oils." 1885, in conjunction with Mr. H. Smith, "Note on the Preparation of Amyl Nitrite." 1886, "Crystallised Aconitine;" also "Note on the Preservation of Ethyl Nitrite." 1887, "Note on the Testing and Purification of Hydrochloride of Cocaine;" also "New Process for the Preparation of Aconitine."

In 1883 John Williams was elected President of the British Pharmaceutical Conference, and delivered an exceedingly interesting presidential address at the meeting at Hastings in the following year.—W. S.

Journal and Patent* Literature.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

New Apparatus for the Concentration of Extracts in vacuo. L. A. Adrian. Bull. Soc. Chim. 1889, 228—234.

As the result of attempts to avoid the decomposition of the organic substances contained in pharmaceutical extracts by heat and exposure to air during concentration, the author describes the following apparatus, by which the evaporation is effected with a minimum amount of change either in colour, taste, or composition. Although the vacuum method has long been employed for the concentration of sugar solutions, the apparatus here described is considerably modified to meet conditions dependent on the nature of the substances under treatment.

The first apparatus, as shown in Fig. 1, was constructed in 1873, and comprises:—

A, the vacuum pan, of about 1,000 litres capacity, is cylindrical and terminated above and below by hemispherical steam jackets. B, a cylindrical reservoir serving as a trap for particles of liquid mechanically carried over during violent ebullition. C, a second reservoir in which the vapours are condensed by a shower of water supplied by the pipe N. S and U are the connecting pipes conveying the vapours which are drawn over by the vacuum maintained through the pipe M. N, a tank containing the liquid to be concentrated. G, a pipe conveying steam to the upper jacket. F, a pipe conveying the steam after use in the upper jacket to the lower jacket. E, a cock for the introduction of cold water along with the steam to the lower jacket, in which any desired lower temperature may be thus maintained. D, outlet for the hot water or steam. R, sight glass to view the course of the evaporation. T, manhole for removing the finished product.

* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.	4d.
Above 8d., and not exceeding 1s. 6d.	1d.
" 1s. 6d., " " 2s. 4d.	1½d.
" 2s. 4d., " " 3s. 4d.	2d.

Fig. 1.

A vacuum having been established in the apparatus, about 150 kilos. of the liquid are let into A, and the heating is regulated by the several cocks and a thermometer inserted into A. To secure tightness in the vacuum pump the pistons work under a cushion of water. The evaporator is fed with liquor until about 25 to 30 kilos. of extract are obtained, when it is removed through the manhole preparatory to introducing a fresh charge. The function of the upper steam jacket is simply to prevent condensation of the

vapours in the evaporator. This apparatus has served with success in concentrating the mother-liquors of sulphate of quinine, but it presented two principal defects, first, that the curved bottom was unsuitable for a quick and complete removal of the finished product, especially if that were quite dry, and secondly, the absence of any kind of agitation was favourable to the formation of a crust on the surface of the liquid which hindered evaporation and required the application of an undesirably high temperature. The

Fig. 2.

oscillating apparatus shown in Fig. 2 was designed to overcome these defects, and has been in successful operation for two years.

A is an evaporator of tinned copper, with a flat bottom and a capacity of 700 litres, the diameter being equal to four times the height. There are two manholes at opposite sides. The evaporator is double-jacketed above and below, D being heated by steam from F, of which the outlet is at G. The pump V injects warm water into the lower jacket, and ejects it through the pipe X, in which a thermometer is placed to register the temperature. The evaporator is hung on an axis Z, resting on the supports M N, and an oscillating motion is communicated by a projecting piece from A, carrying a cam which works in an endless groove in the revolving cylinder Q geared to a shaft driven by a belt. The dome of the evaporator is connected by an india rubber pipe K to the condensing cylinder J, containing 400 tubes through which cold water flows. The products of condensation are collected in C, which is in communication with the vacuum pump by the pipe H. r is one of the sight glasses, to view the course of the evaporation, and to regulate the additions of liquid by the pipe dipping into the tank E. The sides of the evaporator are covered with wood, to hinder condensation within. A charge of 80 litres of liquid is let into the evaporator, and water of 80° into the lower double jacket, steam being let into the upper one. On setting the oscillating movement to work, the evaporating liquid is kept in constant motion, exposing always a fresh surface for evaporation. This condition is very favourable to rapid evaporation and the maintenance of a low temperature, 50 litres of condensed water per hour being easily obtained with a temperature of 35° to 36° C. in the interior of the evaporator, and the desiccation of the residue may be made complete. If the residue be pasty it may be removed through the manhole by tilting the evaporator to one side, and if dry raked out whilst still warm.—G. H. B.

Improvements in Filters. P. A. Maignen, London. Eng. Pat. 17,220, December 14, 1887. *Sd.*

THE inventor claims "the construction of a filtering device consisting of a cloth, such as asbestos, with alternate internal supports and external constrictions, presenting a corrugated surface of large area within a small compass;" also the construction of the internal supports in the form of ceramic or other plates with or without central orifices; also various other devices and combinations; for details of which the drawings must be consulted.—E. G. C.

PATENTS.

Improvements in the Method of and in Apparatus for Purifying Water. A. H. Hobson and C. H. Rooker, London. Eng. Pat. 17,650, December 22, 1887. *11d.*

"A FILTER having an inlet and settling chamber beneath the filter-bed, a water-space above, and an overflow lip, or equivalent dripping device, in a surrounding drip chamber for receiving the filtered water." For further particulars, the three sheets of drawings attached to the Specification must be consulted.—E. G. C.

Improved Machine for making Scorifiers, Cupels, and Crucibles. T. P. Sims, Swansea. Eng. Pat. 445, January 11, 1888. *Sd.*

A VERTICAL cylinder or rod which works in guides carries the mould for the crucible, &c. at the top. This rod receives an up and down motion by means of a crank which connects it with a rotating horizontal shaft. A second vertical rod is situated centrally above the former cylinder, and has a rotatory motion communicated to it by means of suitable gearing which connects it with the rotating horizontal shaft. The lower end of this second rod carries the inner form of the mould. A suitable lump of clay is placed in the mould, and, as this ascends, the

clay is pressed against the revolving internal mould. The rotation of the latter prevents adhesion when the mould with the finished crucible descends. The base of the crucible rests on a movable rod which works like a piston inside the cylinder, and as the latter descends, the descent of this internal rod is arrested and the crucible thus forced out of the mould. The finished crucible can then be easily removed.—F. W. T. K.

Improvements in or connected with Filter-Presses. J. A. Drake and R. Muirhead, Maidstone. Eng. Pat. 1923, February 8, 1888. *Sd.*

To facilitate the passage of liquid from the interior of the filter-press chambers described in Eng. Pat. 10,143 of 1885 (this Journal), the distance rings are provided at their rims, where the plates and frame are in close contact, with a circular and somewhat deep groove, from which slits or channels, radially placed, conduct the liquid freely to the exterior of the apparatus. The filtering plates are sometimes formed from two discs of perforated metal kept asunder by distance pieces, the space between the two plates being tightly packed with bass, coir, coker fibre, or other similar material.—C. C. H.

II.—FUEL, GAS, AND LIGHT.

The Chemical Changes in the Preparation of Water Gas and Heating Gas. J. Laug. Journ. f. Gasbel. 1888, 932. (See also this Journal, 1888, 554—556.)

THE author has examined the action of steam and of marsh gas on pure carbon at various temperatures, and also the conditions under which the resulting products are obtained. Temperatures up to 600° were measured by means of various salts enclosed in small glass tubes, above this by observing the point at which beads of various salts fused on a platinum wire and melted off completely, and the highest temperatures by means of metals. Marsh gas begins to reduce carbon dioxide between 700° and 800° C., at which temperatures 0.6 per cent. of carbon monoxide is formed; at 954° and 1,054° C., 6.4 per cent. and 8.2 per cent. of carbon monoxide were obtained respectively. In each case a separation of carbon was observed in the tube through which the mixed gases were passed; this was also noted on passing marsh gas alone through the tube. The action of marsh gas on steam is small unless a considerable excess of the latter (2:1 or more) is present, when at a temperature of about 1,000° a mixture of gases results consisting of about equal volumes of hydrogen and marsh gas, together with small quantities of carbon monoxide and carbon dioxide. The large amount of hydrogen is due to the direct decomposition of the marsh gas, as well as to the latter being decomposed by the steam; the carbon monoxide results, as in the decomposition of steam by carbon dioxide, by the action of the latter on the carbon deposited in the tube, and its formation begins at 600° C. and becomes considerable at 954° C. The decomposition of steam by carbon starts at 600° C. and is considerable at 1,000° C. Oxygen attacks carbon (gas coke or blast-furnace coke) at 500° C., and provided the former be passed slowly, little or no carbon monoxide is obtained. If, however, a rapid current of oxygen be passed over carbon at this temperature, which is not sufficiently high to cause a reduction of carbon dioxide, the monoxide is formed owing to the higher temperature developed by the combustion of the carbon. On passing a mixture of oxygen and carbon monoxide (containing nitrogen) over coke at 500° C., slowly, carbon dioxide is obtained by the action of the oxygen on the coke, whilst the carbon monoxide passes through unchanged; if the mixed gases be passed over rapidly, a portion of the carbon dioxide formed is reduced, and the resulting mixture contains more carbon monoxide than was originally present. This goes to show that the formation

of the latter precedes that of the former, and if the gaseous mixture be passed very rapidly it takes fire owing to the heat developed by the burning of the coke. Steam acts on coke below 600° C., forming hydrogen and carbon dioxide; nitrogen saturated with steam and passed over coke at 630° C. yields hydrogen and carbon dioxide, together with a little carbon monoxide formed by the reduction of the latter. At 800° to 1,000° C., graphite decomposes steam to a considerable extent, and carbon monoxide is also formed. The author's experiments show that there is a limit to the decompositions expressed by the equations $C + CO_2 = 2 CO$; $C + 2 H_2O = CO_2 + 2 H_2$; and $CO + H_2O = CO_2 + H_2$; for by passing 100 cc. of carbon dioxide slowly over coke at 600° C. for four hours, only 2.3 per cent. of carbon monoxide was formed, and with a rapid current only 2 per cent.; at 1,054° C., 3 per cent. of carbon dioxide remained undecomposed after passing the gas for two hours, and the author was unable to accomplish the complete conversion of the dioxide into the monoxide. Similarly with steam and carbon monoxide there appears a limit to the decomposition, for by passing the mixed gases through a porcelain tube 20 times at 950° C., the decomposition products remained the same as after the mixture had been passed twice, 56.4 per cent. to 62.2 per cent. of the carbon monoxide remaining undecomposed. And finally, steam, when passed over coke, behaves in a like manner. Nitrogen saturated with steam and passed over the coke twice at 1,000° yielded a mixture of carbon monoxide, hydrogen, nitrogen, and a little carbon dioxide, the composition of which suffered little change by passing the gas over the coke 20 times. The formation of the carbon dioxide is due to the action of the steam on the monoxide, whereby the quantity of hydrogen resulting is also increased.—C. A. K.

IV.—COLOURING MATTERS AND DYES.

On the Theory of the Aniline Blue Process. R. Hirsch. Chem. Zeit. 12, 1725—1726.

THE author describes, after some general remarks, an experiment which he made in order to see whether and which aniline blue was formed by the action of paratoluidine on rosaniline. A very pure rosaniline, prepared according to the arsenic acid method, was used, and one part of it heated with five parts of paratoluidine to 190° C. No blue was, however, formed. There was a weak evolution of ammonia, which also takes place when pure aniline is heated with rosaniline, but in neither case did a formation of blue take place. This proves that the presence of an organic acid, such as benzoic or acetic acid, is essential for the formation of the blue, contrary to Nietzki's view that paratoluidine is capable of producing a blue in the absence of an organic acid. The action of organic acids on amines is well known. They form amides, and some further experiments are described to show the action of acetanilide and benzanilide on rosaniline. 10 grms. of rosaniline, 50 grms. of aniline, and 10 grms. of acetanilide were heated to 180° C., and at the end of two hours no blue had been formed. 5 grms. of rosaniline and 10 grms. of acetanilide were heated for two hours to 200° C. There was a faint smell of acetanilide and a trace of blue had been formed (the alcoholic solution appeared, after addition of acetic acid, reddish violet), but the bulk of the rosaniline had not been changed. The theory, therefore, is not admissible, that in the aniline blue process intermediate amides of aniline are produced, which act on the rosaniline and form the new compound. An experiment to convert leuco-rosaniline into leuco-phenyl-rosaniline proved a failure. 10 grms. of leuco-rosaniline, 50 grms. of aniline, and 1 gm. of benzoic acid were heated to 180° C. for two hours, carbonic acid being passed through the flask to prevent oxidation. A small part of the base was, however, oxidised and converted into rosaniline blue, but the bulk of the leuco base had not been acted upon,

and yielded rosaniline on oxidation with chloranil. This observation seems to show that the carbinol group plays an important part in the formation of the blue from rosaniline.—A. L.

On the Preparation of Thiophenols or Thiophenylethers. Leuckart. Chem. Zeit. 12, 1728.

DIAZO-COMPOUNDS acting on salts of mono-, di-, and trithio-carbonic acids are converted into the corresponding thiophenyl ethers, from which the thiophenols can be easily prepared.—A. L.

β-Naphtholsulphide. S. Onufrowicz. Ber. 21, 3559—3563.

THIS substance is manufactured by Dahl and Co. according to the following method:—250 grms. of β-naphthol and 55 grms. of sulphur are heated together to 170°—180°, sulphuretted hydrogen is slowly evolved, and 200 grms. of lead oxide are added gradually. The residue is extracted with alcohol, and the solution deposits crystals on cooling, the analysis of which agrees with the formula $(C_{10}H_6OH)_2S$. The reaction probably takes place as follows:

When boiled with acetic anhydride it yields the diacetate, with benzoyl chloride a dibenzoate. On heating thionaphthol with finely-divided copper in an iron tube to 230°—240° a black mass is obtained, from which β-dinaphthol may be separated.—J. B. C.

The Formation of Durene, and the Application of Aluminium Chloride to the Preparation of Benzylidurene. M. Beaurepaire. Bull. Soc. Chim. 1888, 676—679.

TO prepare durene the author takes 300 grms. of toluene, and 60 grms. of aluminium chloride, and the vapour of methyl chloride is introduced through the bottom of the mixture so that it passes through a column of about 30 to 40 cm. of liquid. The vessel is placed in a calcium chloride bath and warmed. At 60° no action takes place, at 60°—80° methyl chloride is absorbed, but not until the liquid is at 90°—95° does the characteristic reaction of aluminium chloride begin, hydrochloric acid being evolved. The action appears to slacken at 100°, and at 110° products of the anthracene series appear to be formed. At 93°—95°, 400 grms. of toluene yielded 180 grms. of crude durene, the remainder being higher boiling products.

To prepare benzylidurene the author uses a mixture of 10 grms. of crystallised durene, 7 grms. of benzylchloride, 50 grms. of carbon bisulphide, and traces of aluminium chloride, and the mixture is heated until hydrochloric acid is no longer evolved. The product is washed with water, filtered, and distilled in fractions. The principal portion passes over at 300°—350°, and is solid at ordinary temperatures. The pure substance, after recrystallisation from acetic acid, distils at 325°—327°, and has the composition of benzylidurene, $C_6H(CH_2)_4(CH_2.C_6H_5)$.—J. B. C.

Some Derivatives of Paraxyloquinoline. E. Noelting and I. Fruchling. Bull. Soc. Ind. Mulhouse, 1888, 727—729.

THE paraxyloquinoline sulphonic acid prepared from paraxyldine sulphonic acid by Skraup's reaction can only have the constitution represented by the formula—

The crude product is purified by repeated crystallisation from boiling water, and then appears in the form of small white prisms, slightly soluble in cold but very readily soluble in hot water. The barium salt forms small needles, very soluble in boiling water, moderately so in cold water, containing one molecule of water of crystallisation. The potassium salt contains one molecule of water of crystallisation, and is easily soluble. The isomeric xyloquinoline

sulphonic acid was prepared in a similar manner from paraxyldine parasulphonic acid; its constitution is represented by the formula—

This acid also crystallises in small white prisms, but is less soluble in water than the other. Its barium salt forms pearly plates, moderately soluble; according to the conditions of crystallisation it contains either one or two molecules of water. The potassium salt is anhydrous and appears as fine plates, very soluble in water.

These points of difference regarding the solubilities and crystalline forms of the acids and their salts, and the amounts of water of crystallisation contained in the salts, are sufficient to distinguish the two acids. Heated with excess of ammonium chloride, both acids and the barium salts yield paraxyloquinoline, which is, however, more easily prepared from paraxyldine. Paraxyloquinoline is only acted upon with difficulty by sulphuric acid; the monosulphonic acid was obtained by heating the base on the water-bath for 36 hours with five times its weight of sulphuric acid, containing 25 per cent. of SO_3 . This monosulphonic acid was proved to be identical with that obtained from paraxyldine parasulphonic acid.—E. B.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

PATENT.

Improved Process of Manufacturing Artificial Wool from Ramie and other Fibrous Vegetable Matters. R. Haddan, London. From P. Mol, Antwerp, Belgium. Eng. Pat. 9145, June 22, 1888. 4d.

THE object of this invention is to produce a material resembling wool by treating ramie and other fibrous substances for two or three hours with a hot solution of potash, and subsequently with a 10 per cent. solution of bleaching powder for three hours.—E. J. B.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

The Application of Antimony Salts in Cotton Dyeing.
H. Lange. *Färberei Must. Zeit.*, 1889, 35.

THE author recommends the use of the double salt of antimony fluoride and ammonium sulphate, $\text{SbF}_3 \cdot (\text{NH}_4)_2\text{SO}_4$, in cotton dyeing. (See this Journal, 1888, 727.) Cotton mordanted with tannin and this salt gives lighter and brighter colours than when tannin and tartar-emetic are used. An addition of caustic soda of one-fourth to one-fifth of the weight of the double salt may be added, but not more; good results are obtained, and the antimony bath may be used repeatedly, if an addition of the salt is made each time to compensate for the amount precipitated by the tannin. Both the cheapness and solubility in water of this double salt recommend it as a substitute for tartar-emetic; also it can be employed in dyeing mixed fabrics containing half wool or half silk.—C. A. K.

Report on a Memoir of M. Fischli on Turkey-Red Dyeing.
E. Noeltting and F. Binder. *Bull. Soc. Ind. Mulhouse*, 1888, 730—734.

IN this paper, which has been recommended for prize No. 3 offered by the Industrial Society of Mulhouse, M. Fischli states that the chief constituent of the commercial turkey-red oils is ricinoleic acid, either in the free state or combined with alkalis. When the crude article, after being washed with water and freed from uncombined

sulphuric acid, is boiled with dilute hydrochloric acid, the sulphuric acid compound is decomposed, sulphuric acid being liberated and ricinoleic acid formed. This fact is confirmed by Benedikt. For the purposes of this research ricinoleic acid was prepared pure, as shown by the analysis of its barium salt, and was found to give coloured lakes quite as bright as those obtained with the commercial oleines.

Taking a known quantity of the alkaline ricinate and gradually adding aluminium sulphate or acetate to it, a viscid semi-fluid precipitate was first obtained; continuing the addition of aluminium salt, the precipitate clotted, and after purification by solution in ether, evaporation to dryness, and washing with alcohol, it became pulverulent. Thus purified the aluminium ricinolate, on analysis, was found to correspond to the formula $\text{Al}_2\text{O}(\text{OH})_2(\text{C}_{18}\text{H}_{33}\text{O}_2)_2$. The aluminium ricinolate heated in water with alizarin begins to attract the colouring matter at 40° C. (confirmed in dyeing), then melts, and gradually, whilst the temperature is increased to 105° C., takes a bright red appearance.

The lake so formed is unaltered by boiling with soap; alcohol and ether after prolonged action dissolve it, and these solutions can be used for dyeing samples of cotton turkey-red.

After making these preliminary experiments the following process of dyeing was adopted:—

1. Preparing with oil. 2. Mordanting with alumina.
3. Fixing with chalk. 4. Dyeing. 5. Preparing with oil.
6. Steaming. 7. Soaping.

Preparing with Oil.—For this operation ammonium and sodium ricinoleates were used. At a high temperature the fibre fixes the fatty acid and allows the ammonia to escape; only partial decomposition takes place on drying at 50°—60° C. The sodium ricinate under the same conditions is decomposed, ricinoleic acid being liberated and carbonate of soda formed by the action of the fibre and the air.

The fatty mordant when fixed, particularly if pure ricinoleic acid has been used, does not, as shown by analysis, undergo oxidation.

Mordanting.—Different aluminium salts are in use. On padding with the acetate the cloth acquires a sticky touch, due to the formation of the above-mentioned aluminium ricinolate. After drying, Fischli washed with water and found aluminium acetate in solution, showing that complete fixing of this mordant does not take place. A second extraction with alcohol yielded a mixture of fatty acid and aluminium ricinolate capable of mordanting cotton for pink. Further, cellulose precipitates alumina.

Fixing with Chalk.—The purpose of this process is to precipitate the aluminium salt and to deposit a certain amount of lime on the cloth.

Dyeing.—The dyed fabric, on testing, gave the following results:—

On treatment with alcohol, a powdery red substance remained, corresponding to the colour-lake less its fatty constituent, which was removed; furthermore, a soluble colour, aluminio-ricinoleic lake, was formed, capable of dyeing unmordanted cotton a rose tint.

When a ricinolate is added to the dye-bath, the dyed fibre contains free ricinoleic acid in addition to the two substances mentioned.

Preparing with Oil.—This process is unnecessary when a ricinolate is added to the dye-bath. Unless such addition is made, the tissue has a brownish appearance. No action takes place on padding and drying.

Steaming.—According to Fischli's experiments, air at 105° C. has no action, whilst, when steam is present, the colour brightens instantly. This change is due to the action of the fatty matter on the alizarin-lime-alumina lake, and microscopic examination shows that steaming favours the penetration of the fibre by the colouring matter. The first oil preparation causes the penetration to be less thorough. Immediately after steaming, the cloth has a sticky touch on account of the presence of a portion of the lake in a melted state and of an excess of fatty matter.

Brightening.—The tin salt used along with the soap in this operation has a chemical action, tin entering into com-

bination with the lake and increasing its brightness. The brightening process is useful after dyeing with alizarin or anthrapurpurin; it can well be omitted in the case of flavopurpurin. Flavopurpurin, according to the author, is most suitable for calico printing, seeing that only a simple soaping is requisite to brighten it.

The latter part of the memoir deals with the process of discharging in pattern by the bleach-bath. It is shown that alizarin on being so destroyed yields phthalic acid, the bleach-bath acting like other oxidising agents. Alizarin offers most resistance to discharging in this way, then anthrapurpurin, and, lastly, flavopurpurin. Finally, it is remarked that the phenomena mentioned above take place when dyeing with the sulphocates; and the decomposition of these bodies, on steaming, into fatty acid and sulphuric acid, is described.—E. B.

Industrial Society of Malthouse. Report of the Meeting held November 14, 1888.

CHARLES KOFF read a paper on starch and its derivatives, giving an account of the manufacture of maize and wheat, starch, dextrin, calcined farina, and British gum. To these direct derivatives of starch must be added glucose in the form of clear syrup, solid glucose, and crude dextrose of 75 per cent., refined dextrose of 80 per cent., and, finally, a liquid maltose. A firm in Alsace now prepares soluble starch and starch gums of great purity, which, for many purposes, are capable of replacing *gum-arabic* and *gum-senegal*. Soluble starches are formed by the action of sulphur dioxide on starch under pressure, and at a high temperature. The liquid mass thus obtained is clarified completely and made perfectly colourless, and then evaporated in vacuo. It is lastly dried by warm air. With hot water the soluble starches give sticky and gum-like liquids; they also turn iodine blue. *Tragantin* is soluble in cold water. They are suitable for fine finishing, for printing paper and textiles, and for confectionery. The *gommes universelles*, prepared from starch, are soluble in hot and cold water. They have all the properties of gum-arabic. Prudhomme submitted a paper in which he describes the spontaneous decomposition of dinitrosoresorcinol on standing into a brown paste, soluble in water, and which gives with acetate of chromium a fast steam colour. It withstands light and acids very well. It is probable that the dinitroso-compound was not pure when prepared, as it is very stable in the pure state.—J. B. C.

On Potassium Antimony Oxalate. R. Wagner. Chem. Zeit. 12, 1726.

According to Lensen and Souhay this salt, formerly called tartar-emetic substitute, consists of—

on heating to 100° C. it loses 6 molecules of water. The author examined a commercial product, which he found sufficiently pure for analysis. His analysis led him to the formula $\text{Sb}_2(\text{C}_2\text{O}_4)_3 + 3\text{K}_2\text{C}_2\text{O}_4 + 8\text{H}_2\text{O}$. On heating to 75° C. it loses 2½ mols. of water; the rest escapes at 130° C. If heated to a higher temperature it is rapidly decomposed.

—A. L.

Paraphenylene Blue—A New Fast Blue for Cotton. R. B. G. Chem. Zeit. 12, 1748—1749.

PARAPHENYLENE blue belongs to the class of indulines which are soluble in water, and is obtained by the action of the diamines of the benzene series upon amidohydroxy compounds. In dyeing, the cloth is mordanted with 4 per cent. of tannin and then worked in a bath of chromium acetate of ½°—10° B. to which 2 per cent. of tartar-emetic is added. After two hours standing the cloth is washed and dyed in paraphenylene blue. It is better to add a further quantity of the blue when the bath is nearly exhausted. Excellent results are always obtained. The colour has many advantages. It dyes yarn and woven

goods equally well and evenly, gives a fine deep blue, and can be mixed with other aniline colours so as to give a variety of shades. The colour is faster than indigo.

—J. B. C.

On Indophenol Indigo Vat. E. Noelting. Chem. Zeit. 13, 191.

HITHERTO the application of indophenol in dyeing has been very limited. The blue has not the indigo shade, and is too easily decomposed by acids. Lately, Durand, Huguenin, and Co. made the remarkable discovery that a mixed indigo indophenol vat yields very excellent results. They proceed in the following way: 66 litres of indigo ground with water (corresponding to 20 kilos. of solid indigo; 6½ kilos. of indophenol; 96 kilos. of sodium bisulphite, 39½—40° B.; 13½ kilos. of tin protochloride crystals ($\text{SnCl}_2 + 2\text{H}_2\text{O}$); 16½ kilos. of zinc dust; and 660 litres of water, are mixed and stirred well for one hour. Then 52 litres of caustic soda, 38° B., are added, and the mixture once more stirred and allowed to stand to the following morning. The concentrated vat thus obtained is poured into the dye vat containing 5,500 litres of water and 340 litres of hyposulphite. The dye vat has to be kept always at the same strength. This can be easily done by allowing some of the concentrated vat to run through a funnel into the dye vat. In the evening, some solution of hyposulphite is added to the vat to prevent oxidation during the night. The hyposulphite solution is prepared by gradually adding 160 grms. of zinc dust, 200 grms. of tin crystals to 1 litre of bisulphite of 39—40° B. and 4 litres of water. These vats work continually, as there is nearly no precipitate. After dyeing it is better to pass through a cold bath, containing 2½—3 per cent. of bichromate. Cotton yarn is dyed as usual; wool is dyed from the warm vat. The saving of indigo in this process is considerable—at least 25 per cent.; 55 kilos. of indigo and 15—19 kilos. of indophenol have the colouring power of 100 kilos. of indigo. The shades are brighter, and the mixed vat also dyes "dead" cotton.

For printing, the following paste is recommended: 10 litres of starch solution, 10 kilos. of potassium bichromate, 7½ litres of ammonia 20°—21° B., and 3 kilos. of china clay, the goods being afterwards passed through a bath of sulphuric and oxalic acids at 50°—55° C. for ½—¾ of a minute. For coloured printing, albumen colours are used as with indigo, only the quantity of bichromate has to be increased.—A. L.

PATENTS.

Improvements in Machinery or Apparatus for Felling, Washing, Scouring, Cleaning, Beating, Softening, and Beetling of Yarns and Textile Fabrics. W. A. L. Hammersley, Leek. Eng. Pat. 15,097, November 5, 1887. 8d.

In this improved machine, the bunks of yarn, working on horizontal "rice heads," made of brass or other bars, and loose adjustable or weighted rollers, are passed in front of buffers (inclined at an angle of 5° to the perpendicular to avoid undue strain on the yarn), against which they are banged by means of beaters mounted on a rocking shaft and worked by an eccentric. Perforated pipes are suitably arranged for delivering water or other liquid against the yarn or fabric. For details and modifications the specification must be referred to.—O. H.

Improvements in Printing Paper, Paper-hangings, Calicoes, other Woven Fabrics, Warps, and Oil-cloths. J. Walker and H. Carver, Pendleton. Eng. Pat. 2838, February 25, 1888. 8d.

THE purpose of this invention is to dispense with the use of "doctors" in the printing of paper and calicoes. In the usual way, the colour is applied to the engraved portion of the copper rollers, and the excess of colour removed from the unengraved surface by means of "doctors." By this invention the colour is supplied to the unengraved surface

of the rollers, the engraved portions remaining free from colour. This is effected as follows: The printing colour is supplied from a box or trough containing a wooden roller which dips into the colour. In contact with this roller is an india-rubber-covered colour-carrying roller, which latter is in contact with two india-rubber-covered colour-distributing rollers, these distributing rollers being also in contact with the surface of the engraved printing roller. The amount of colour supplied to the carrying roller is regulated by a smaller roller also fixed in the colour box, but above the surface of the colour itself. By means of adjusting screws this roller is pressed against the colour-supplying roller and the amount of colour supplied is regulated by this pressure. The distributing rollers are mounted in links to facilitate removal for cleaning, and are held in position by regulating screws. Rotary motion is imparted to the roller in the box and to the carrying rollers in contact with it by means of toothed wheels geared up with the engraved roller. It is claimed that by this invention a finer and clearer impression can be obtained upon paper, calico, &c. than has hitherto been possible.—W. E. K.

Improvements in Apparatus for Dyeing or Scouring Yarn. C. L. Klander, Philadelphia, U.S.A. Eng. Pat. 16,756, November 17, 1888. 8d.

This is an improvement on Eng. Pat. 8803 of 1887. (This Journal 1887, 595.) The yarn is supported on two sets of transverse bars in a suitable frame or wheel, which by its rotation moves the yarn in and out of the dye-liquor. The outer set of bars are also themselves adapted to rotate so as gradually to move the position of the yarn on the bars, and by a mechanical arrangement of pivoted stop and regulating spring a bell is rung to warn the workman when any stoppage in this rotation of the hanks occurs. For details the specification and accompanying drawings must be consulted.—W. E. K.

Improvements in Dyeing Woollen and other Woven or Felted Fabrics. J. W. Bannister, Leeds. Eng. Pat. 17,347, November 29, 1888. 4d.

For the purpose of dyeing woollen fabrics in one vat, without the employment of a mordant, a vat is prepared by dissolving copperas, bluestone, soda, and oxalic acid in hot water; logwood and fustic are then added to this solution, and in the vat thus prepared the goods are dyed in one operation.—W. E. K.

1887. Schlösing, 31 August, Eng. Pat. 11,821.

1888. Neu-Stassfurt, additional patent to 3,673, 22 October, S. 4353 Ger. Pat.

The author exposes these patents to criticism, and for the same object carries out extensive experiments in the laboratory by special methods to find out the chemical behaviour of magnesium chloride when heated.

Magnesium chloride solution can only be evaporated to form $\text{MgCl}_2 + 6 \text{H}_2\text{O}$, after which decomposition into hydrochloric acid sets in.

On heating it further to 550°C . all the water can be driven off, but about 50 per cent. of the chlorine is also driven off as hydrochloric acid and a magnesium oxychloride remains, corresponding to MgO , MgCl_2 .

THERMOCHEMICAL DATA OF MAGNESIUM CHLORIDE.

$\text{MgCl}_2 + 6 \text{H}_2\text{O}$	32,970 cal.

I.—FOR HYDROCHLORIC ACID.

Negative.	Positive.
MgCl_2	151,010 cal.
$\text{MgCl}_2 + 6 \text{H}_2\text{O}$	32,970 "
One H_2O decomposed	58,161 "
5 H_2O evaporated	58,800 "
	<u>301,004 "</u>

For decomposing $\text{MgCl}_2 + 6 \text{H}_2\text{O}$ into MgO , MgCl_2 and $5 \text{H}_2\text{O}$.

— 301,004
+ 146,994
— 110,007

Calories have to be introduced.

II. FOR CHLORINE.

In case all $6 \text{H}_2\text{O}$ can be driven off as such:—

Negative.	Positive.
MgCl_2	151,010
$\text{MgCl}_2 + 6 \text{H}_2\text{O}$	32,970
$6 \text{H}_2\text{O}$ evaporated at 156°	70,632
	<u>254,612</u>

therefore for $\text{MgCl}_2 + 6 \text{H}_2\text{O}$ there have to be introduced:—

— 254,612
+ 146,992
— 107,620

Calories.

Under the theoretically most favourable conditions in both cases a large quantity of heat must be introduced for decomposition, and for all the processes the fuel required will prove a great expense, especially as these reactions do not take place at the ordinary temperature, but at 550°C .

HYDROCHLORIC ACID.

In order to manufacture hydrochloric acid from magnesium chloride liquor, the large quantity of water contained therein must be reduced. This is done by evaporation to 45°B . at a temperature of 156°C ., which is equal to $\text{MgCl}_2 + 6 \text{H}_2\text{O}$.

As in further heating only 50 per cent. of the chlorine are obtained as hydrochloric acid, more water must be introduced to obtain a complete decomposition, although the theoretical formula:—

shows plenty of water present originally for complete decomposition. The following methods for manufacturing hydrochloric acid are possible.

I. Heating the $\text{MgCl}_2 + 6 \text{H}_2\text{O}$ from outside and introduction of steam over the salt during the heating.

II. Mixing $\text{MgCl}_2 + 6 \text{H}_2\text{O}$ with such salts as lose their water only at a red heat, and subsequent heating of these mixtures, and recovery of the salts.

III. Heating $\text{MgCl}_2 + 6 \text{H}_2\text{O}$ by direct flame, and either using a coal containing a large quantity of water, or mixing steam with the combustion gases.

Group I. comprises the following patents:—

Clemm, 1864, W. Weldon, 1871, Heinzerling and Schmid, 1887.

The advantages consist in an easy condensation, and the purity of the hydrochloric acid.

The disadvantages are numerous.

The whole of the heat necessary for decomposing and heating up must be introduced from outside, and this is so much the more difficult, as the furnace cannot be constructed of iron on account of its corrosion by the acid which is heated above 500°C .

The steam, moreover, must of necessity be superheated to avoid cooling of the furnace, and lastly the steam does not penetrate the mass, but passes over it. This renders a quick decomposition difficult on account of want of contact, not even rendered possible by agitation.

Group II.—G. Eschellmann, 1881; E. Bohlig and Heyne, 1886; and Konther, 1887.

The difficulty of these patents consist in extra cost entailed in heating the mixture, and the cost of the recovery of these salts.

The Bohlig and Heyne patent also possesses all the disadvantages of Group I., and the acid produced by it is contaminated by organic substances.

Group III.—Solvay's Patents, 1877—1888; Randohr, 1879; W. Weldon, 1881; Randohr, Blumenthal and Co., 1881; A. Vogt, 1885; Neu-Stassfurt, 1885; Neu-Stassfurt, additional patent, 1888; and Vereinigte Chemische Fabriken Leopoldshall, 1887.

The advantages of this group consist in the substitution of the heating up from outside by direct contact of the combustion gases with the magnesium chloride, and the omission of the separate superheating of the steam.

The considerable difficulties consist in the complete condensation of the hydrochloric acid to high strength. This acid will also be contaminated by the combustion gases, and the firing has to be carefully superintended to avoid excess of oxygen in the combustion gases which would set chlorine free.

If these difficulties can be overcome, the patents of Neu-Stassfurt and Vereinigte chem. Fabriken Leopoldshall might possibly lead to the successful manufacture of hydrochloric acid for purposes of sale, if the fuel does not reach too high a figure.

A probable cost of this hydrochloric acid of 20° B. would be 15s. per ton.

In case this acid is used for manufacturing bleaching powder by the old Weldon process, a ton of bleaching powder would cost, in Stassfurt, 5*l.* 5s.

The Weldon-Pechiney process, as far as it concerns the manufacture of hydrochloric acid from magnesium chloride, cannot be classed under any of these three groups, as it involves a principle of its own as regards the decomposer used.

The conditions for a successful manufacture of hydrochloric acid seem to be overcome by this process; they are:—

1. Good contact between steam and magnesium oxychloride by forming the pieces.
2. The heating up from outside and the disadvantages of direct contact of the combustion gases with the oxychloride are avoided by storing the heat in the furnace for decomposition and heating up, which take place simultaneously.
3. Good condensation.
4. The decomposer is built of fire-clay, which withstands the highly-heated hydrochloric acid gas.
5. Purity and strength of the acid for sale.

The disadvantages are:—High consumption of fuel, dealing with large masses of material, and expensive plant.

However, these disadvantages are common to all magnesium chloride processes.

CHLORINE.

The patents for direct production of chlorine are:—

Tilgman, 1847; Clennu, 1864; Solvay, 1877—1888; Randöhr, 1879; Weldon, 1881; Randöhr, Blumenthal, and Co., 1881; Weldon-Pechiney, 1884—1887; Vogt, 1885; Konther, 1887; Heinzerling and Schmid, 1887; Schlösing, 1887.

The following conditions have to be observed in manufacturing chlorine direct:—

I. The magnesium chloride liquor must be converted into a form which allows the air to penetrate it for oxidation.

II. The six equivalents of water must be reduced as much as possible, to obtain a minimum of hydrochloric acid.

III. The oxychloride must be heated up quickly to the oxidising temperature.

Point I. Surface oxidation is impracticable on account of the length of time required and the weakness of the chlorine produced.

The only material which brings the liquor into a convenient oxidisable form, and which allows the recovery of the magnesia also, is magnesia itself.

Point II. is obvious.

Point III. It is not impossible to heat up large masses from the outside to a red heat, but only at the expense of much time and fuel, on account of the bad conductivity of the oxychloride for heat. These operations cannot be carried on in iron vessels on account of the corrosion of the iron by chlorine and hydrochloric acid gas. To line such vessels with fire-clay is very difficult on account of the difference of expansion between fire-clay and iron, which difficulty is the greater the larger the dimensions of such apparatus. In addition to this, the bad conductivity for heat of such a lining has to be considered.

During the oxidation the oxychloride falls to dust. For all these reasons a quick heating up is imperative.

Pechiney carries these points out practically in his decomposer.

Schlösing proposes an oxidiser which is continuous and utilises its heat by gradually raising that of the oxychloride. The whole of the heat for heating up and oxidising is introduced by superheated air of 760° C. The possibility of this is proved by calculation. In case the oxychloride as briquettes does not fall to dust altogether, this oxidiser might prove a practical success.

The manufacture of the anhydrous magnesium oxychloride, according to the first part of the patent, yields 37 per cent. of the chlorine contained in the original $MgCl_2 + 6 H_2O$ as hydrochloric acid. Taking into consideration this quantity of hydrochloric acid, and the practical difficulties to be encountered, the success of this part of the process is doubtful.

The only process besides this, which is worth a detailed criticism, is the Weldon-Pechiney process. It carries out practically the conditions for a successful chlorine manufacture as well as possible.

The process consumes, per 35.5 grms. of chlorine,—

	Calories.
For oxidation of the dried oxychloride.....	85,626
For drying the oxychloride.....	37,617
Total.....	123,243

This necessitates a large consumption of fuel, but this is common to all such processes.

By adding magnesia, it converts the magnesium chloride into an oxidisable form, and makes possible the recovery of the magnesia from the decomposition product in a useful form.

The reduction of the water in the magnesium chloride is also carried out to a large extent.

The difficulties of separate heating up and oxidising are overcome by carrying on both operations collaterally, and storing the necessary heat in the walls of the oxidiser.

There are still many improvements possible, and the following points deserve consideration:—

(1.) It is impossible to entirely avoid the evolution of hydrochloric acid in the drying of the oxychloride, and this acid will have to be condensed in Germany and England.

(2.) The decomposer might need more repairs after heating into a still higher temperature than at present (1,000° C.).

(3.) If highly superheated air could be used for oxidation, economy of time and improvement in the volume per cent. of the chlorine obtained would result.

(4.) The hydrochloric acid gas in the chlorine might be advantageously absorbed by magnesia, as described in Mond and Eschellmann's patent (Ger. Pat. 44,109, 13 January 1888), and by oxidising the oxychloride, this hydrochloric acid would be transformed into chlorine.

(5.) The oxidation might be carried out in Schlösing's oxidiser, the use of which, however, depends on the possibility of moving the oxychloride.

(6.) The chlorine volume per cent. of 6—8, are good enough for bleach making.

(7.) The cost of a plant is twice as much as with the old Weldon's process, and time must decide how much the repairs will influence the cost of production per ton of chlorine.

One ton of bleaching powder by the Weldon-Pechiney process would probably cost—

£ s.
3. 10 in Stassfurt.
4. 5 in Hamburg.

if the figure of 5*l.* per ton of chlorine in Stassfurt can be realised.

With the success of the Weldon-Pechiney process the magnesia process for producing chlorate of potassium by Muspratt and Eschellmann's patents will supersede the old lime process.

The advantages of this process combined with the Weldon-Pechiney process consist in—

(1.) The whole of the chlorine and magnesia being recovered, minus mechanical losses.

(2.) The production of 92 per cent. of the chlorate, against 70 per cent. by the lime process, being as near to the theoretical yield as can be practically expected.

Messrs. J. Muspratt and Sons, in Widnes, have carried out this process for three years quite successfully on a weekly production of 12 tons, and the process has answered all expectations.

The cost per ton of chlorate by the combined processes in Stassfurt is 26*l.*, without general expenses, &c.

According to the author, no other proposed process for producing chlorine from magnesium chloride, except the Weldon-Pechiney process, is capable of a commercial practical success, unless the future brings further inventions, which, however, would have a difficult position in contending it with the Weldon-Pechiney process.—G. E.

PATENTS.

Improvements in the Treatment of Sulphide of Calcium for the Purpose of obtaining Sulphide of Ammonium and Sulphuretted Hydrogen. E. H. Parnell and J. Simpson, Liverpool. Eng. Pat. 2831, February 25, 1888. 6*d.*

In the first operation of the "Parnell and Simpson process" (this Journal, 1885, 198) calcium sulphide is distilled with an excess of a dilute solution of ammonium chloride. In order to economise the latter it is desirable to avoid an excess, and by proceeding in a special manner, which forms the feature of this invention, the sulphur of the calcium sulphide can be obtained without even using as much ammonium chloride as corresponds to the chemical equivalent of the calcium sulphide. If calcium sulphide and water be subjected to the pressure of steam, at a temperature of 300° F., it is decomposed into calcium hydrate and sulphuretted hydrogen. This fact is made use of in the process of distillation. Ammonium chloride and an excess of calcium sulphide are heated in a still of sufficient height to give the temperature and pressure necessary for decomposing the calcium sulphide, and when steam is passed through the apparatus, the calcium sulphide is thus not only decomposed by the ammonium chloride, but also by the heat and pressure of the steam with liberation of sulphuretted hydrogen and ammonium sulphide. It is found that it is possible to extract the sulphur in the calcium sulphide with about half its chemical equivalent of ammonium chloride.—S. H.

Improved Economic Treatment of certain By-Products of Gas and Tin-Plate Manufactures. E. Bowen, Pontardulais. Eng. Pat. 3179, March 2, 1888. 4*d.*

This invention relates to the treatment of the liquor used in "pickling" iron and steel plates in the process of the tin-plate manufacture. When this solution has done a certain amount of work it becomes unfit for further use, and now consists of water, sulphuric acid, and iron sulphate. According to this invention this liquor is mixed with the ammoniacal liquor of the coal-gas manufacture. The result is a solution of ammonium sulphate and a precipitate of iron in the form of hydrate and carbonate. After separating the precipitate the sulphate of ammonia is obtained by evaporation, whereas the precipitate is calcined and converted into iron peroxide for use as a pigment or otherwise.—S. H.

Improvements in Apparatus for Treating Ammoniacal Liquor. H. Green, Preston. Eng. Pat. 3428, March 6, 1888. 8*d.*

This apparatus consists of two parts, the "free ammonia evolver" and the "fixed ammonia evolver." By means of a syphon and float arrangement a regular and continuous flow of ammoniacal liquor is made to enter a horizontal pipe, where it is heated by contact with a steam pipe. Ammoniacal gas is thereby given off which passes away to a saturator. The liquor then passes on to a series of communicating annular chambers, into which milk of lime is introduced for liberating the fixed ammonia, steam and agitation at the same time assisting the operation. The ammoniacal gas given off flows to the same saturator, which is of conical form at the lower part. The pipe for admitting

the ammoniacal gas is fixed near the lower end, whereby the contents of the vessel is set in motion. Below the saturator a tumbler on trunnions is provided, to receive the contents of the saturator. By tilting the tumbler the liquor can be poured off and the salts allowed to remain until they are dry, or nearly so.—S. H.

An Improved Process of Manufacturing Soda by means of Ammonia, and Producing Carbonate of Soda, Caustic Soda, and Hydrochloric Acid or Chlorine. A. M. Clark, London. From J. B. Daguin, Paris, France. Eng. Pat. 3668, March 9, 1888. 8*d.*

The process consists essentially of the following operations and reactions:—

(I.) A mixture of solutions of sodium chloride and ammonium sulphide in suitable proportions is treated with carbonic acid, whereby sodium bicarbonate is precipitated, ammonium chloride remaining in solution and sulphuretted hydrogen being liberated, $2 \text{NaCl} + (\text{NH}_4)_2\text{S} + 2 \text{CO}_2 + 2 \text{H}_2\text{O} = 2 \text{NaHCO}_3 + 2 \text{NH}_4\text{Cl} + 2 \text{H}_2\text{S}$.

(II.) The sodium bicarbonate is calcined, giving off carbonic acid for use in the first operation—

(III.) The filtrate from the first operation, containing all the ammonium chloride, is boiled with barium sulphide, barium chloride being formed and ammonium sulphide given off, which is absorbed in brine for use in the first operation—

(IV.) The barium chloride is treated by one of the following methods:—

(a.) Sulphuretted hydrogen and air are passed at a red heat over barium chloride, obtained by evaporation of the solution, thus: $\text{BaCl}_2 + \text{H}_2\text{S} + \text{O} = \text{BaSO}_4 + 2 \text{HCl}$.

(b.) Sulphuretted hydrogen is burnt and the gases given off caused to bubble through a solution of barium chloride: $\text{BaCl}_2 + \text{SO}_2 + \text{O} + \text{H}_2\text{O} = \text{BaSO}_4 + 2 \text{HCl}$. This reaction will only take place in the presence of certain chlorides, such as the chlorides of manganese, copper, iron, &c., which promote, catalytically, the oxidation of sulphurous acid.

(c.) Barium chloride is treated either in the dry way or in the humid way with manganese peroxide, and subjected to the action of sulphuretted hydrogen or sulphurous acid:—

(V.) The barium sulphate produced in the fourth operation is reduced by charcoal to sulphide, partly for use in the third operation. Another portion of the sulphide is boiled with water, when it is decomposed into barium hydrate and sulphhydrate, the latter of which replaces a certain amount of sulphide in the third operation, whereas the barium hydrate is used for causticising sodium sulphate or carbonate. It will be seen that the feature of the process is the circumstance that the whole of the ammonia, baryta, sulphur, and carbonic acid, with the exception of that which passes away with the sodium carbonate, are recovered.—S. H.

A Process for Facilitating the Oxidation of Sulphurous Acid for the Manufacture of Sulphuric Acid and of Hydrochloric Acid and Chlorine, and for other Industrial Purposes. A. M. Clark, London. From J. B. Daguin, Paris, France. Eng. Pat. 3669, March 9, 1888. 6*d.*

This invention relates to a process for facilitating the oxidation of sulphurous acid by means of oxygen or air. The process consists essentially in treating a mixture of sulphurous acid and air in the presence of salts of manganese, copper, iron, or tin. It appears that these salts act catalytically and favour the rapid oxidation of sulphurous acid. This process is therefore applicable for the manufacture of sulphuric acid, and in the second instance for the direct manufacture of hydrochloric acid or chlorine.

1. *Manufacture of Sulphuric Acid.*—Sulphurous acid and air are caused to bubble through a solution of the sulphates of manganese, copper, iron, or tin, or caused to traverse a column filled with coke and impregnated with any of the solutions mentioned. In both cases the resulting liquid contains sulphuric acid, mixed with the sulphate employed.

11. *Manufacture of Hydrochloric Acid and Chlorine.*—Any chloride is treated with sulphurous acid and air in the presence of a catalytic agent; the following reactions take place :

The catalytic agent, in this case manganese chloride, is always regenerated. If manganese peroxide be present at the same time, the hydrochloric acid acts on it, producing free chlorine.—S. H.

Fig. 1.

channels, and are each provided at one end with a spur wheel V, all of which are made to gear with each other. A worm wheel W, geared with the worm X on the driving shaft Y gives rotatory motion to the stirrers. The lime is charged through the hopper E and travels slowly to the other end of the channel A, where it falls through a branch F into the channel B. Here it is conveyed back to the other end, and so forth, until it is eventually discharged through the shoot I. The chlorine gas enters the lowest channel D through a lateral inlet K, and passing through the channel, is brought into intimate contact with the lime, as it is raised up by the stirrers. The gas then rises through the branch L, into the channel C, and so forth, until it gradually arrives at the top channel, where any unabsorbed residue escapes at O. The hopper E has a kind of throttle-valve, by means of which the discharge of lime into the hopper is regulated. On the side of the channels openings are left, which can be tightly closed by covers P, and allow of a ready inspection of the interior of the channel.—S. H.

Improved Apparatus for subjecting Pulverulent or Granular Materials to the Action of Gases. R. Hasenclever, Aachen, Germany. Eng. Pat. 17,012, November 22, 1888. 6d.

THE apparatus is designed for the manufacture of bleaching powder, or more especially for the absorption of chlorine by slaked lime. It mainly consists of a series of horizontal channels, each provided with stirring and propelling arrangement. These channels are made to communicate with each other and with a gas supply in such a manner that the lime fed into one end of the first channel passes consecutively through all the channels, while the gas travels at the same time in the contrary direction. Fig. 1 shows a sectional side view; Fig. 2 an end view and cross-section of the apparatus. A, B, C, D are a series of superposed channels. The stirring arrangement consists of a shaft T with a large number of oblique radial blades U. The ends of the shafts are carried in bearings in the end covers of the

Fig. 2.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

Cryolite and its Substitutes in Glass Manufacture.

R. Zsigmondy. Dingl. Polyt. J. 271, 36—44 and 80—88.

CRYOLITE is used in the manufacture of milk or opal glass, and its price has risen so considerably within the last three years that it is most desirable to find a substitute for it. Attempts have been made to use a mixture of felspar and fluorspar for this purpose, with more or less success, while Weinreb has employed alkaline fluorides prepared from fluorspar by fusion with sand and an alkali. The objection to this process is the cost of the alkali if potash be used, and the outlay needed for fuel if soda be selected, as sodium fluoride requires 23 parts of water for its solution, all of which has to be evaporated to obtain it from the aqueous extract of the melt. Before describing his own modification of this process the author discusses the various

explanations of the action of cryolite in producing a milk glass that have been advanced. In 1869 *Benrath* attributed it to the expulsion of the fluorine as silicon fluoride and the liberation of the alumina which was distributed in suspension throughout the glass, while *Williams*, in the same year, postulated the formation of sodium fluosilicate from the fluorides of silicon and sodium produced by the action of the cryolite on the silica of the glass, and considered the opacity of the product due to it.

Ebell, in 1877 (*Dingl. Polyt. J.* **225**, 77), demolished both these theories by showing the presence of fluorine to be essential to the formation of a milk glass, while sodium fluosilicate was unable to effect it in the absence of alumina. He was followed by *Weinreb* in 1885 (*Dingl. Polyt. J.* **256**, 362), who demonstrated the necessity for both sodium fluoride and alumina. Finally *Schwarz* (*Dingl. Polyt. J.* **267**, 223) repeats *Williams'* statement that sodium fluosilicate is the cause of the opacity.

The author considers aluminium fluoride to be the essential constituent, and upholds his view by showing that the work of the previous observers can be interpreted in accordance with it. He confirms *Weinreb's* statement that sodium fluoride, alone, is ineffective, and points out that a great economy of fluorine may be attained by providing sufficient basic material to combine with the silica and prevent it expelling the fluorine as silicon fluoride. A good cryolite glass may be represented thus:—

The author succeeded in producing opaque glasses by the use of kaolin and fluorspar, which were little inferior to those containing cryolite, but in preparing them the bottom of the pots became deeply pitted, owing to the fluorspar melting first, trickling down through the mass of the other constituents and attacking them; pots were thus sometimes perforated in a couple of days.

Further attempts to use fluorspar instead of cryolite, being unsuccessful, attention was directed to the *partial* replacement of the latter, and with better results. For example, the following mixture yields a good milk glass:—

	Parts.
Sand	100
Potash	7.1
Soda	12.2
Fluorspar	7.4
Cryolite	7.4
Orthoclase	7.1
Kaolin	1.9

Eleven parts of felspar may be substituted for the last two constituents, in which case somewhat less sand and potash should be used.

Schwarz gives the analysis of a similar glass, which is, however, free from alumina, but contains zinc. The author contends that this does not invalidate his statement as to the cause of the opacity of cryolite glass, as zinc fluoride, like aluminium fluoride, lead fluoride, calcium phosphate, and stannic oxide, remains suspended and undissolved in the glass mixture when solidified, and thus communicates to it its peculiar property. A "French opal" glass examined by *Huck* (*Dingl. Polyt. J.* **224**, 624) contained:—

	Per Cent.
SiO ₂	63.7
PbO	16.5
FeO	0.3
Al ₂ O ₃	16.8
K ₂ O	2.3
	99.6

As it is free from fluorine, the author considers its opacity due to the presence of lead, as in lead glasses (perhaps on account of the low temperature at which they fuse), alumina is less soluble than in those not containing that metal.

In spite of the difficulties attending their manufacture, especially the outlay in melting-pots, glasses containing fluorspar instead of cryolite are a commercial success, on account of the high price of the latter body. Such a glass, giving satisfactory results, is represented by the formula $\frac{3}{4} \text{K}_2\text{O}, \frac{1}{4} \text{CaO}, \frac{1}{4} \text{ZnO}, 6 \text{SiO}_2, \frac{1}{4} \text{Al}_2\text{F}_6$. But even the best

of these glasses is not equal to good cryolite glass, as they are apt to lack homogeneity, and are not of such an opaque white colour as the latter. Moreover, they make much waste, which, in some manufacturers' opinion, eats up all profit arising from the use of the cheaper material. The conclusion arrived at is, that a fluorine compound free from lime and of low price can be the only formidable competitor to cryolite.

The details of the author's proposed process are as follows:—

Fluorspar is fused with potash and silica, the melt extracted with water, and the hot concentrated solution of potassium fluoride obtained, precipitated with a solution of soda saturated at about 38° C. Sodium fluoride is thrown down, while potassium carbonate remains in solution, and may be recovered and used over again. In order to discover the best proportions for obtaining a high yield of potassium fluoride, it was necessary to make many trials of different mixtures, and to estimate the quantity of soluble fluoride they yielded, and for this purpose a quick and fairly accurate method of determining fluorine was requisite. The principle made use of by *Knöfler* for the determination of combined sulphuric acid (*Annalen*, 1885) was employed, standard calcium chloride solution being substituted for barium chloride. The solution containing the fluoride, together with potassium silicate and carbonate, was neutralised with hydrochloric acid in the hot, using phenolphthalein as an indicator; 1 cc. of $\frac{N}{10}$ sodium carbonate solution was added, and then an excess of $\frac{N}{10}$ calcium chloride solution. (The use of the single cc. of sodium carbonate solution is to indicate when all the fluoride has been precipitated as CaF_2 , as then, and not till then does the sodium carbonate react with calcium chloride, precipitating calcium carbonate, which is neutral to phenolphthalein.) The excess of calcium chloride was determined by adding $\frac{N}{10}$ sodium carbonate solution until the liquid became alkaline, indicating the presence of excess of sodium carbonate consequent on the complete precipitation of the calcium chloride, then filtering and titrating back with hydrochloric acid, using methyl-orange as an indicator. Of course the 1 cc. of sodium carbonate must be added to the main quantity used when calculating the results. Obviously, only the first and last neutralisations need be effected accurately, the other two being merely devices to indicate that an excess of the reagent has been added.

To demonstrate the value of this method it was necessary to ascertain:—

(1.) How HF comported itself towards indicators when titrated. (2.) How water glass behaved towards indicators when titrated with HCl. (3.) Whether water glass, neutralised with HCl, had any action on CaCl_2 .

It was found with regard to (1) that litmus and phenolphthalein changed colour at a point corresponding to the formation of normal fluorides. Methyl-orange showed a tendency to change when enough alkali had been added to form acid fluorides like KHF_2 , but was far from distinct. For (2) it was proved that water glass behaves like pure carbonated alkali; the separated silica had no action even on phenolphthalein. In respect of (3), experiment answered it in the negative.

This being so, the method was tried on mixtures, like those that would have to be dealt with, containing known quantities of fluorine. It was found to give a maximum error of 1.5 per cent. of the quantity of fluorine estimated, which was sufficiently near for the purpose in hand. Thus a solution of hydrofluoric acid, which indicated 0.1022 grms. HF by titration with caustic soda, and 0.1021 grms. by weighing the CaF_2 , it could form, gave by titration 0.1016, 0.1005, and 0.1020 grm. in three trials.

A convenient modification of the process, if the quantity of alkaline carbonate and silicate present be wholly unknown, is to divide the extract from the melt into two parts, titrate one with standard hydrochloric acid, using cochineal or litmus as an indicator, and then run a little more than the quantity of acid thus found into the other half, boil, and titrate back with caustic soda, using phenolphthalein as an indicator until the red colour appears, which is then

removed by a single drop of hydrochloric acid. By this means the difficulty of titrating a solution containing a carbonate, with phenolphthalein as an indicator, is got over.

Armed with this method, the author proceeded to determine by numerous experiments the conditions under which the best yield of alkaline fluoride was obtained. He found that if less than 2 mol. of K_2CO_3 to 1 mol. of CaF_2 were used, as much as 1 mol. of SiO_2 was necessary to get 70–80 per cent. of the CaF_2 decomposed. Besides this, the degree of intimacy of the mixture, the temperature employed, and time occupied, were important factors in the yield. The portion of the melt left on extraction with water consists of calcium silicate, carbonate, and fluoride, together with small quantities of potassium salts which it is difficult to remove completely. Such a mixture could be used in glass making, and therefore no part of the process yields an absolutely waste product.

To prove the practicability of the other half of the process, potassium fluoride was precipitated with the equivalent quantity of sodium carbonate in the hot. The sodium fluoride, being somewhat soluble, prevented so good a yield as could be wished being obtained.

On considering the cost of the process it is seen that the potash is used repeatedly, the soda corresponding to the sodium fluoride, replacing that which would otherwise have to be added to the glass as carbonate, while the silica can be used in the form in which it is left, viz., calcium silicate, to replace the sand generally necessary. This leaves only the fluorspar and the fuel to be bought each time, and they are both cheap compared with cryolite. The process promises to be lucrative, unless mechanical difficulties are encountered. One of these, namely, the need of a material to form the floor of the furnace in which the fluorspar, sand and potash are to be melted, capable of withstanding their action, might be met by the use of basic bricks like those now obtainable at iron works.—B. B.

Improvements in the Production of Pictures and Designs on China, Earthenware and Glass. J. B. G. Bonnard, London. Eng. Pat. 1751, February 6, 1888. 6d.

A SHEET of glass is sensitised with a mixture of water, uracil, potassium bichromate, and borax, and exposed under an ordinary photographic transparency. The design is then brought out by dusting on the necessary colours, which are fixed by means of a fatty composition consisting of essence of lavender, fatty essence of Venice, and powdered resin. The picture is coated with a similar mixture containing collodion instead of essence of lavender, and placed in an alkaline bath of borax and sugar after previously soaking in warm water. The film can be then transferred to the china, or other material placed in the bath, which is afterwards fired in the usual way.—O. H.

Improvements in the Manufacture of Glass. E. Story and R. Punshon, London. Eng. Pat. 2184, February 14 1888. 6d.

THE inventors manufacture glass from "granite, granulite, syenite, elvan, &c." silicate of soda, sulphate of soda, carbonate of soda, and asbestos being among the other substances used.—E. G. C.

Improvements in the Silvering of Glass. J. Syer, Manchester. Eng. Pat. 16,453, November 13, 1888. 4d.

THIS process consists in the deposition of silver on glass from one or two solutions containing silver salts, without the application of heat. The solutions contain nitrate of silver, ammonia, and Rochelle salt.—E. G. C.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

On Saccharine Matter in Mortar and on Building in Frost. S. Crompton. Engineer, 1889, 110.

A CASE is quoted in the experience of the author of some building done in sharp frost. The courses of brickwork set in the wall with sugared mortar were perfectly sound and were untouched by the frost and by the thaw which followed it, whilst the work below it, and the work done on the same day that the sugared work was done, but done with unsugared mortar, suffered severely.

He further points out that the reason that Roman mortar was so good and stood so well, is, that the lime was slaked in pits and allowed to remain there for two or three years before use. He quotes Pliny (A.D. 77) in proof of this.

—W. S.

X.—METALLURGY, MINING, Etc.

On Corles' Method for Reducing difficultly Reducible Oxides. E. v. Sommaruga. Chem. Zeit. 12, 1728–1729.

THE author believes that the method for reducing oxides of aluminium, silicon, and other elements, by means of an electric current in the presence of carbon, is simply a true reduction by carbon at a very high temperature, and not an electrolytic process. (Compare this Journal, 1886, 206–210.)—A. L.

Huntington's Centrifugal Roller Mill. Engineer, 1888, 519.

THIS new type of crushing mill possesses several important advantages over the ordinary stamp battery. A ten-stamp battery, with 850 lb. heads, weighs, in all, from 12 to 14 tons, and costs 650*l.*, while a 5-ft. Huntington mill weighs 5½ tons in all, the cost, including erection, being 350*l.* Omitting the great advantage in transport, the latter can be erected in 15 working hours by two men, the former by four men in 30 days, while frequently a considerable time is required before it can be got in action. Further, with one-half the power, the output of the centrifugal mill is 10–50 per cent. higher than the stamp battery. It consists chiefly of a vertical spindle, on which is keyed a circular frame, and from the latter, suitably hung in bearings permitting of a radial motion, with regard to the vertical spindle, are yokes carrying the steel rollers, while between the rollers, and attached to the frames, are scrapers. When the machine is in action these steel rollers are pressed by centrifugal force against a steel ring forming the sides of the pan. The quartz is fed with water into a hopper, and, being carried by the scrapers and the water against the sides of the ring, is pulverised by the rollers; the precious metal amalgamates with the mercury run in the bottom of the pan, while the fine grit, without slime, is discharged through a perforated grating extending along half the circumference of the mill, and passes on to the concentrators in the usual manner. About 75 per cent. of the precious metal is retained by the amalgam.—O. H.

The Artificial Production of Chrome Iron. S. Mennier. Compt. Rend. 107, 1153–1154.

THE author has succeeded in obtaining chrome iron artificially by very strongly heating an intimate mixture of 148 grms. of potassium bichromate, 58 grms. of ferrous carbonate, and 56 grms. of iron filings, the reaction being expressed by the equation—

The mixture is contained in an earthen crucible previously dusted with finely powdered cryolite. On breaking the fused mass distinct zones are visible, one of which is finely grained and steel grey, almost entirely composed of small

regular octohedrons, sometimes passing even into the cube, and yields, on analysis, the numbers for chrome iron.

—G. H. B.

Improvements in Metallurgical Processes. Dingl. Polyt. J. 271, 17—25 and 109—118.

At Freiberg lead is extracted in a very crude state, owing to the number and variety of residues from the working of ores of other metals that are added to it during smelting. The following table shows how complex a mixture it is:—

	I.	II.	III.	IV.	V.
Silver.....	1.790	0.470	0.131	0.830	0.516
Copper.....	0.662	0.225	0.121	0.328	0.660
Bismuth.....	0.034	0.019	0.022	0.017	0.032
Cadmium.....	0.002	..	0.003
Tin.....	1.490	1.354	0.078	0.650	0.871
Arsenic.....	1.159	1.826	0.131	0.540	0.388
Antimony.....	6.215	0.958	0.180	0.976	0.358
Nickel and cobalt	0.010	0.011
Iron.....	0.005	0.007
Zinc.....	0.003	0.002	0.008
Sulphur.....	..	0.051	0.015

Of these—

I. is from the rich (in silver) lead ore from the Muldner works.

II. is from the ordinary lead ore from the Muldner works.

III. is from the working up of the slag from the Muldner works.

IV. is from the lead ore from the Halsbrückner Works.

V. is from the working up of the slag from the Halsbrückner works.

The process of purification is as follows:—

About 90 per cent. of the copper is first separated by liquation, which gets rid of the nickel, cobalt and iron at the same time; with these latter remains a part of the sulphur and arsenic. The tin, arsenic, and antimony are separated as lead stannate, arseniate, and antimoniate respectively, by means of the "improving" process, a jet of air being allowed to play on the surface of the fused lead. The yield of metal in this case is 74—82 per cent. in the case of the lead from lead ore, and 78—90 per cent. in that of the product obtained by working up the slag. The silver is then extracted by the Pattinson or Parkes process, or by a combination of the two. The composition of the zinc-containing layer, skimmed off and removed, if the Parkes process be used, is shown by the following analysis of three samples of it:—

	I.	II.	III.
Gold.....	6.024	0.006	0.003
Silver.....	3.82	3.33	1.69
Copper.....	3.28	0.49	0.36
Bismuth.....	0.01	0.01	0.01
Lead.....	56.45	44.54	44.52
Zinc.....	34.02	49.69	50.77
Iron.....	1.31	0.57	0.85
Antimony.....	Trace.	Trace.	..
Sulphur.....	Trace.
Oxygen, &c.....	1.09	1.37	1.80
	100.00	100.00	100.00

An experiment on the way in which the impurities in crude lead disposed themselves when the metal was kept fused, was made by A. Schertel, to whom all the above analyses are also due. An iron cylinder one metre in height was filled with the fused lead and allowed to remain in a chamber kept at a temperature above the solidifying point for 24 hours. It was then allowed to cool, and samples taken from the top and bottom. They gave on analysis the following impurities:—

	Top.	Bottom.
Silver.....	0.121	0.103
Copper.....	1.324	0.031
Bismuth.....	0.132	0.042
Tin.....	0.911	?
Arsenic.....	2.161	1.980
Antimony.....	0.700	0.719
Iron.....	0.103	0.009
Nickel.....	0.029	..
Zinc.....	0.016	0.003
Sulphur.....	0.500	..
Specific Gravity.....	10.321	10.824

An analysis of the Freiberg blue vitriol is given, showing a percentage of 99.801 of $\text{CuSO}_4 + 5\text{H}_2\text{O}$, the balance being made up of traces of ferrous, zinc, nickel, and lead sulphates. The white arsenic produced contains 99.70 to 99.88 per cent. of As_2O_3 . The vitriol, which is one of the by-products at Freiberg, contains 0.175 per cent. of arsenic; after treatment of the chamber acid with sulphuretted hydrogen, the acid of 66° B. contains only 0.0002 per cent. The quantity of lead in the strong acid amounts to 0.058 per cent.

C. Schnabel considers (*Zeits. Ver. deutsch. Ing.* 1888, 758) that the electric method for the deposition of lead fine is not reliable.

C. H. T. Havemann has devised a process for the extraction of lead and silver from their sulphides without the necessity for a preliminary roasting. It consists in the fusion of the ore with caustic or carbonated alkali, which combines with the sulphur and liberates the metal. If the ore be free from iron it is advisable to add 5 to 10 per cent. of iron or its sulphide in order to form a double sulphide of iron and sodium, which facilitates the subsequent disintegration of the slag, which is extracted with water, and at the same time treated with CO_2 from a kiln or other suitable source, whereby the alkaline carbonate is regenerated; it may then be causticised and used over again. In working the process, charcoal and litharge may be added to the melt, and thus a larger yield of lead obtained for the same quantity of soda. A mixture of sodium chloride, litharge, and water may also be used with the view of obtaining caustic soda *in situ*. If silica be present in the ore to be smelted, it will not cause loss of soda, as the silicate of soda formed will be recovered as carbonate by the treatment with CO_2 mentioned above. The furnace used, if lined with siliceous bricks, will be strongly attacked by the alkaline melt, but can be made capable of resisting corrosion by previous treatment with a small quantity of soda at a much higher temperature than that needed in the process, thus transforming its surface into a refractory one of mixed silicates.

It is found that a galena containing about 70 per cent. of lead, together with silica and sulphides of copper, zinc, antimony, and iron, requires about 25 per cent. of soda.

The inventor reckons the cost of the recovered soda at 40s. per ton, *i.e.*, 10s. per ton of ore. The conditions under which the process is most likely to be commercially successful are those obtaining in a country where fuel is scarce, as it promises to be economical in that respect.

In 1886 North America produced 127,008 tons of lead.

At the Muldner works, Freiberg, the lead is desilverised by a combination of the Pattinson and Parkes processes; this is necessary on account of its impurity, particularly in respect of bismuth. The crude lead has first to be freed from copper, nickel, cobalt, tin, arsenic, and antimony, because the first three would cause more zinc to be used in the Parkes process than would otherwise be needed, while the others would remain in the desilverised lead and require to be removed by subsequent refining. The lead thus purified is also suitable for treatment by the Pattinson method. But for the presence of bismuth the Parkes process would be used exclusively, but as it does not eliminate this metal, recourse must be had to the other method, it being desirable to extract the bismuth, both on account of its deleterious influence on lead and its intrinsic value. Accordingly the Pattinson process is used until the percentage of silver is reduced from 0.8 or 0.4 to 0.1 per cent., at which stage the bismuth is all present in the concentrated lead, and then the desilverising completed by the Parkes method. *A. Junge (Jahrb. f. Berg. und Hüttenwesen, 1888, 1—12)* deals with the question of the best way of combining the two processes. He shows that working with a battery of 16 pots, of which No. 1 contains more than 0.81 per cent. of silver, and No. 16, 0.001 per cent. of silver, the cost of working crude lead containing so much silver as to be put into any one of the pots from No. 2 to No. 6, is greater than that of working a lead of any other degree of richness. (The cost for these particular pots is about 120 pfennige per cub. metre, that of the others being about 80 pfennige for the same quantity.) Further, the cost of the Parkes process, reckoning the expenditure for zinc not recovered by distillation, wages, fuel, repairs, royalty, and carriage, comes to an average of about 90 pfennige per cub. m. (1 pfennig = $\frac{1}{100}$ th shilling), for the same class of lead that would be put into pots 2—6 in the Pattinson process. It also appears that the expense increases less rapidly than the percentage of silver in the lead dealt with. On the other hand, as all qualities of lead take up the same quantity of zinc (viz., 0.7 per cent.), which can only be recovered by refining, poor leads are best treated by the Pattinson process.

The question of the bismuth has, however, to be considered, and as it collects in the silver-rich pot (No. 1) in the Pattinson process, it is found best to use this process *before* the Parkes process instead of *after*, as one would expect from the statements above. Consequently at Freiberg a battery of eight or seven pots, according as the lead goes into No. 2 or No. 3 at the beginning of the operation, is used, by which means a lead containing 2 per cent. of silver is obtained in No. 2, and one with 0.1 per cent. in the last. The poor lead is then desilverised by the zinc process in cast-iron pots, the resulting zinc-lead-silver alloy removed and liquated

in cast-iron liquation pots, the desilverised lead freed from zinc by partial oxidation (refining), and the liquated zinc-lead-silver alloy distilled in plumbago crucibles to recover the zinc.

The percentages of the products calculated on the crude lead are:—

(1.) 0.35 per cent. of “schlicker” that separates spontaneously from the crude lead on its first being melted; it contains 0.0004 per cent. of gold and 0.1 per cent. of silver, and goes to be melted down with a new batch of lead ore.

(2.) 2.25 per cent. of rich zinc-lead-silver alloy with 0.0153 per cent. of gold, 4.051 of silver, 53.2 of lead, 2.68 of copper, and 39.7 of zinc.

(3.) 98.95 per cent. of desilverised lead, containing 0.75 per cent. of zinc, and 0.0007 per cent. of silver.

(4.) 1.5 per cent. of lead recovered by liquation from the zinc-lead-silver alloy before it is distilled. It contains 1.3 per cent. of zinc, and 0.032 per cent. of silver, and is returned to the desilverising pots.

The process lasts 20 hours altogether, five hours being occupied in melting and skimming the lead, and five hours for each desilverising after the addition of the zinc, which is made in three portions.

The liquation of the zinc-lead-silver alloy cannot be pushed to its extreme possible limit with advantage, as the product is bulky and much loss is incurred in the distillation, which is carried out as follows: the alloy mixed with 1 per cent. of coarsely-powdered wood charcoal is put into plumbago crucibles as mentioned above (the bottoms of which are covered with a thin layer of charcoal), and heated in a furnace for eight or nine hours; 100 parts yield 57.17 parts of rich lead, containing 0.0186 per cent. of gold and 7.35 per cent. of silver; 5.85 parts of slag left in the crucible containing 0.112 per cent. of gold and 3.5 per cent. of copper; 29.54 parts of reguline zinc; and 7.22 parts of zinc dust containing 6.35 parts of zinc; 90.4 per cent. of the zinc present is recovered, corresponding to 50 per cent. of the whole quantity used for desilverising.

The respective merits of Schnabel's ammonia process and the method described above, are still the subject of dispute; the former is said to be preferable where the output is large.

Roessler has devised a process (Ger. Pat. 45,195 of 1888) by which the distillation can be effected at a sufficiently low temperature to permit of iron vessels being used. It consists in driving hydrogen, carbonic oxide, gaseous hydrocarbons, nitrogen, or carbon dioxide, through the fused alloy. The first four expel the zinc in the metallic state, the last as oxide, for which purpose it is preferable to steam, which, in presence of air, oxidises a portion of the lead.

(To be continued.) —B. B.

PATENTS.

Improvements in the Extraction of Gold and Silver from Ores or Compounds containing the same, and in Solvents for such Metals. A. Parkes, Dulwich. Eng. Pat. 17,033, December 10, 1887. 6d.

This patent, in which there are 11 claims, consists in submitting the crushed ore to the action of any one of the following mixtures, preferably with the assistance of steam under pressure:—(1) bromine, cyanide of potassium, and dilute chromic acid; (2) fluorine, cyanide of potassium, and dilute chromic acid; (3) bromine, chlorocyanide of potassium, and water; (4) bromine and dilute hydrochloric, nitric, sulphuric, or chlorochromic acid; (5) bromine, chlorine, and water; and (6) bromine (or fluorine), alcohol, and water. The precious metals are afterwards obtained from solution by any known method.—A. W.

Improvements in the Manufacture of Aluminium, and Apparatus therefor. H. H. Lake, London. From C. Netto, Dresden, Germany. Eng. Pat. 17,532, December 20, 1887. 11d.

The claims are various improvements in the methods of submitting aluminium compounds to the action of sodium,

for the purpose of obtaining aluminium. The first plan is to introduce sodium into the melted mixture contained in a crucible with a tight-fitting lid, repeatedly turning over the whole. The next is the use of a revolving cylinder with a flue through its centre, in which gas is burnt to supply the heat. The mixture is melted in this cylinder, sodium run in, the vessel closed, the flue disconnected from the gas-supply pipe, and the whole revolved. Again, the sodium can be brought to bear on the mixture by means of a "diver." Also, the operation can be conducted on the principle of Heaton's process for steel making, using sodium in place of the nitre and an aluminium grid in lieu of iron.

Finally, two forms of apparatus are described for introducing the sodium at the bottom of the molten aluminium compounds on the Bessemer converter plan. The materials are melted, run into the hot converter, and melted sodium is forced in by pumps, either through the bottom or through a pipe which leads down the centre of the converter to the bottom, where it is distributed through a perforated plate. The molten aluminium mixture may also be poured on to the melted sodium, preferably by first dividing it by pouring through a kind of sieve. Drawings of the inverting crucible, the revolving cylinder, and the converters are given.—A. W.

Improvements in the Manufacture of Bronze. W. H. Beck, London. From A. Sentex, C. Maréchal, and A. Saunier, Paris, France. Eng. Pat. 1886, February 8, 1888. 6d.

This is a process for producing "malleable and ductile bronze" bars or plates which are free from cracks and blowholes, are "inexhaustible," and which may be "rolled and drawn with the greatest ease." Moreover, the metal has the appearance and "sonorosity of gold." One and a half kilos. of tin are purified by melting under nitre. Ten kilos. of copper are melted and 50 grms. of equal parts of nitrate and cyanide of potassium are added for the double purpose of reducing the oxides and "fattening" the metal. Then 25 grms. of bitartrate of potassium, with the same quantity of cyanide, are added, and after polishing, the tin is introduced; 25 grms. each of sal-ammoniac and cyanide are thrown on, 1 gm. of "phosphuret of copper" introduced to "impart mildness," and 20 grms. of "Marseilles soap" added, which still further "fattens" the metal. Finally, 1 gm. of sodium is added at the moment of casting. The metal, if cast in sand, may contain more tin, and if the proportion of tin be reduced, the quantity of phosphorus and sodium may be increased.—A. W.

Improvements in Apparatus suitable for Separating Gold from its Ores. J. Hornsby and G. E. Coupe, Grantham. Eng. Pat. 1914, February 8, 1888. 8d.

This improvement is intended to ensure the intimate contact with amalgamated silver plates of sludge containing gold, especially when a large amount of water has to be used with the ore. The sludge is introduced into a box, preferably lined with amalgamated plates, and having inside it an axis or drum provided with easily removable tangential or other arms carrying amalgamated plates. These plates are caused to revolve in the casing, being either driven from the outside or made to revolve like a water-wheel by the sludge itself, the latter method being especially suitable for ores which require to be mixed with a large quantity of water. At the bottom of one of the sides of the casing is a slit, closed by a plate which dips into a trough of mercury. Other plates are provided at the bottom of the casing to break the flow of sludge, so as to prevent a too violent flow carrying the mercury out of the trough.—F. W. T. K.

A Mode of Treating Manganese Ore for Convenience and Economy in Transportation and Shipment. H. Morris, Manchester. From A. W. de Leuse Lenczewsky, Koutaïss, Russia. Eng. Pat. 1939, February 9, 1888. 4d.

The manganese ore is pulverised, worked up into a paste with water, made into bricks, and calcined sufficiently to remove the moisture and "a good portion of the foreign substances without melting out the metallic manganese." In some cases it may be found convenient to calcine the powdered ore directly and ship the powder.—F. W. T. K.

A New Non-Magnetic Metallic Alloy. H. Ostermann and A. Prip, Geneva, Switzerland. Eng. Pat. 11,939, February 16, 1888. 4d.

The alloy is composed of a mixture of platinum, nickel, copper, wolfram (tungsten), cobalt, and cadmium in certain proportions. The alloy is very suitable for replacing steel in the works of watches and in watch escapements, for it is both non-magnetic and its coefficient of linear expansion is almost the same as that of steel. By varying the proportions the alloy can be made harder or softer, more or less ductile and malleable, &c. (See next page).—S. G. R.

Improvements in the Extraction of Gold, Silver, and Platinum from Auriferous and Argentiferous Materials. F. Trickett and J. Noad, London. Eng. Pat. 2778, February 24, 1888. 6d.

The patentees make a saturated "solution of chloride of sodium and oxide of manganese," by dissolving 12 parts of the former and 1 part of the latter in 24 parts of water, and pass through it an electric current "until the whole of the chlorine is liberated and taken up by the solution, leaving a residue of sodium oxide." The ore is heated with the chlorine solution so obtained, whereby gold, silver, and platinum are converted into "soluble chlorides." Pyrites is first "mixed with the said residue of sodium oxide" to remove sulphur previous to the treatment with the chlorine solution. The metals can be obtained from solution by any known method.—A. W.

Improved Economic Treatment of Certain By-Products of Gas and Tin-Plate Manufactures. E. Bowen, Pontardulais. Eng. Pat. 3,179, March 2, 1888. 4d.

See under VII. page 193.

Improvements in Alloys containing Iron or Steel. J. F. Hall, Sheffield. Eng. Pat. 3410, March 6, 1888. 4d.

The inventor adds metallic nickel to iron in proportions of from 2.5 per cent. up to 50 per cent. of the whole, the greatest amount previously used being not more than 3 per cent. The alloy, which can be cast, forged, or rolled, is said to be particularly adapted for cannon, gun barrels, shot and shell, armour plates, engravers' plates, and other purposes.—S. G. R.

Improvements in Plating Iron and other Metals with Aluminium. L. Q. Brin, Paris, France. Eng. Pat. 3548, March 7, 1888. 6d.

The plate or piece of metal to be coated with aluminium is placed in a muffle furnace, which can be heated to 1,000°—1,500° C., and covered with a flux formed of clay, or other earth rich in alumina, mixed with sodium chloride, fluor-spar, and borax. In the muffle itself, or preferably in another vessel, aluminiferous vapours are produced by heating aluminium chloride or a mixture producing the chloride, and, in the latter case, passed into the muffle furnace. The vapours are mixed with a strongly heated inert gas to prevent condensation and deposition of the aluminium chloride before reaching the muffle; nitrogen obtained by passing air over incandescent coke answers well for the purpose. The aluminium formed permeates the other metal to a greater or lesser extent according to the temperature and time employed. If the outer layer of aluminium be removed it is found that the mass is still so impregnated with aluminium as to possess practically all the properties of an alloy of that metal.—S. G. R.

Improvements in the Process and Apparatus for obtaining Alloys of Aluminium and particularly Aluminium Bronze. L. Q. Brin, Paris, France. Eng. Pat. 3549, March 7, 1888. 8d.

Iron, steel, or other metal can be alloyed with aluminium, which has been reduced directly from its ore, in the following manner. The metal is coated over with a mixture of clay

or ore rich in aluminium, chloride of sodium, borax, and fluorspar, and then placed in a blast furnace with alternate layers of fuel. The aluminium is readily reduced and combines with the other metal or metals. The alloy formed in the case of iron and aluminium has a low melting point, and can be also produced in an ordinary reverberatory furnace without the use of a blast. The gases issuing from the throat of the furnace are passed through water to retain any products carried off by them.

—S. G. R.

Improvements relating to the Separation or Extraction of Metals from their Ores by Amalgamation, and to Apparatus therefor. T. R. Jordan, London. Eng. Pat. 3965, March 14, 1888. 11d.

This patent is for a new amalgamator, and is accompanied with drawings. The apparatus consists of a series of inverted conical plates placed one above the other on a spindle. Round these cones is a casing with a series of annular shelves sloping downwards towards the centre, and so arranged that a shelf is situated above and below each central cone. The cone plates and the shelves are amalgamated. The pulp is fed in at the top, the spindle carrying the cones made to revolve, and the amalgam collected in a suitable box at the bottom of the machine. Fresh mercury is also fed in at times at the top of the apparatus. It is maintained that the centrifugal force of the revolving inverted cones is sufficient to carry the pulp up and over the inclined surface on to the shelves of the casing, down which it is washed on to the next inverted cone underneath, and so on, the ore by this means being subjected to an extensive rubbing action against the amalgamating surfaces.

—A. W.

Improvements in the Manufacture of Metallic Alloys or Compounds. J. C. Bull, Erith. Eng. Pat. 4086, March 16, 1888. 6d.

THE improvements relate especially to zinc alloyed with other metals. In order to obtain an alloy with iron, manganese, chromium, tungsten, &c., which have much higher melting points than zinc, the inventor adds to the zinc-bath either varying proportions of arsenic and phosphorus, or preferably the former alone. With a bath containing 5 per cent. of arsenic, an alloy containing 18 per cent. of iron can be obtained, the highest result previously obtained being 10 per cent. of iron, and then only with a large loss of zinc. The melting point of the zinc varies with the amount of arsenic added. The surface of the molten zinc should be covered with fine coke in order to prevent free access of air.—S. G. R.

Improvements in the Treatment of Metallic Ores, and in Apparatus employed therein. G. J. Atkins, London. Eng. Pat. 4430, March 22, 1888. 8d.

THE finely-crushed gold or silver ore is fed through a hopper into a pipe, through which a jet of steam mixed with chlorine or bromine, &c., or mixtures to produce these bodies, is passing. The ore by this means is thoroughly disintegrated, the fine particles of metal being attacked by the chlorine and the whole carried forward by the force of the steam into a receiving chamber, where setting and condensation take place. The gold is in solution, and the silver may be extracted by lixiviation with hyposulphite or cyanide. The gold solution is passed through a carbon filter through which a current of electricity is passing, whereby, it is maintained, the gold is more completely precipitated than when the carbon filter alone is used. A diagrammatic sketch of the plant is given.—A. W.

Improvements in or relating to the Manufacture of Sodium and Potassium. G. A. Jarvis, St. Georges. Eng. Pat. 4842, March 31, 1888. 6d.

IN order to prevent the large amount of corrosion which takes place when iron crucibles or tubes are used, the inventor proposes the use of fire-clay apparatus. The

crucibles or retorts must be lined with some refractory basic material impermeable to the metallic vapour. The most suitable is that made from strongly-burned magnesia, with the addition of 10 per cent. of fluorspar; this is rammed in tightly, forming a firm coherent lining. If desired, sheet-iron may be enclosed between the crucible and this lining. The carbon necessary for reduction is prepared from a mixture of small charcoal, coke, or coal, made up with pitch, and then moulded and burned on iron bars, as supports, forming coherent carbon rods. These are placed in the retorts. If iron crucibles or other apparatus are to be employed, as is usually the case, they should be surrounded with salt, or some other suitable fusible material, by which the external corrosion of the iron is almost completely prevented.

—S. G. R.

A New Metallic Alloy. H. Ostermann and C. Lacroix, Geneva, Switzerland. Eng. Pat. 11,940, April 19, 1888. 4d.

THE alloy is to be used in place of steel, especially in the manufacture of springs, balance-wheels, and the other parts of watches, &c., which are liable to be affected by magnetism or oxidation. The following is the mixture:—Gold, 30 to 40 parts; palladium, 30 to 40 parts; rhodium, $\frac{1}{10}$ to 5 parts; copper, 10 to 20 parts; manganese, $\frac{1}{10}$ to 5 parts; silver, $\frac{1}{10}$ to 5 parts; and platinum, $\frac{1}{10}$ to 5 parts.—A. W.

A New Non-Magnetic Alloy. H. Ostermann and C. Lacroix, Geneva, Switzerland. Eng. Pat. 11,941, April 25, 1888. 4d.

THE proportions in this case are:—Gold, 30 to 40 parts; palladium, 30 to 40 parts; copper, 10 to 20 parts; silver, $\frac{1}{10}$ to 5 parts; cobalt, $\frac{1}{10}$ to $2\frac{1}{2}$ parts; wolfram, $\frac{1}{10}$ to 5 parts; rhodium, $\frac{1}{10}$ to 5 parts; and platinum, $\frac{1}{10}$ to 5 parts. This alloy is specially suited for watch escape-ments, and it secures the compensation of the balance-wheel and hair spring in different temperatures.—A. W.

An Improved Method of Calcining Pyrites and other Gold-bearing Ores. D. Hutton, Adelaide, South Australia. Eng. Pat. 12,683, September 3, 1888. 6d.

THE improvement consists in injecting steam, or solutions to produce the same, through the bed of the furnace into the pyrites during the process of calcination, whereby the resulting mass is rendered more friable and capable of being finely crushed with greater facility and less expense.

—A. W.

Improvements in the Process of, and Apparatus for extracting Iron from its Ores, and in obtaining By-Products. H. H. Eames, Baltimore City, U.S.A. Eng. Pat. 14,837, October 16, 1888. 8d.

THE apparatus consists of a raised cylindrical vertical chamber heated by the products of combustion of a furnace, and in which are vertically placed a number of narrow cylindrical retorts which protrude through the top and the bottom of the said chamber. The tops of these retorts are provided with hoppers, and to the lower extremities may be attached movable receptacles. The retorts may be of iron lined with fire-clay, and inside of each are placed two rods of carbon at the opposite sides of the interior throughout the entire length. These carbons are connected with the two extremities of a dynamo. The charge—consisting of oxide of iron, carbon, and lime—is introduced into the retorts, which are then closed and rendered air-tight. The whole is heated to about 550° C. and a current of electricity passed through each retort. The iron oxide is reduced to metal, the gases escape through suitable traps, and the sulphur and phosphorus are said to be eliminated in the following manner:—Part of the oxygen of the ore combines with the sulphur of the ore and produces sulphurous acid, which, in turn, combines with the lime and produces sulphate of lime, and the phosphorus is likewise liberated with the production of phosphate of lime. This "liberation continues until all

the said combined matter is carried off, when the refined ore may be discharged into the vessels" underneath each retort.

It is maintained that "sulphide ores of iron" may be used in these furnaces. In this case it is not necessary to mix in carbon and limestone, but simply to submit the ore itself to the continued action of heat and electricity. By this means "pure sulphur" is produced, which runs down into the underlying receptacle, and the iron is left in the "pure state."—A. W.

An Improved Process of Separating Metals and other Substances from Molten Slag and the like. H. H. Lake, London. From O. B. Peck, Chicago, U.S.A. Eng. Pat. 17,068, November 23, 1888. 8d.

This is a process for separating shots of metal, matte, and metallic compounds, from slags by means of a centrifugal machine. A wide-neck squat bottle-shaped vessel lined with cast iron is supported on a spindle and made to revolve rapidly. The molten slag is poured in at the top, preferably in a continuous stream; the metal, &c. is driven to and accumulated at the wall of the machine, which is kept cool by an external stream of water, and the freed slag rises to the neck of the vessel up the centre, through which it passes, and is then thrown off. The operation, of course, may be stopped at any time, but it is preferable to work it continuously until a large accumulation of metal has taken place. The latter solidifies, and the machine, which can be made up of parts clamped together, is taken to pieces and the metal removed. A drawing of the apparatus is given.—A. W.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

Accumulators. Duneau. Electricien, 1889, 13, 32.

To avoid the deterioration of the lead plates in accumulators, the author covers them with a conducting deposit which is not attacked in any way by sulphuric acid. To effect this, the lead plate is placed as the anode in an alkaline bath of a lead salt, a second piece of lead serving as the cathode; by passing a weak current through the solution, the anode becomes covered with a dense and even deposit of the black oxide of lead, which protects the metal most effectually. Lighter and harder metals than lead might be employed by this method.—C. A. K.

PATENTS.

Process for Recovering Zinc and Alkali from Spent Liquors of Lalande Voltaic Batteries. H. A. Fergusson, London. Eng. Pat. 1707, February 4, 1888. 6d.

In the Lalande battery, zinc is used as one electrode, with a caustic alkali solution as electrolyte. The inventor places the spent liquor in a bath with iron and zinc alternately as electrodes, and, by passing an electric current, causes pure zinc to be deposited from the liquor on to the zinc plates in flocculent masses, which can be collected and separated from the liquor by filter-pressing, and afterwards be formed into blocks or ingots by pressure or fusion; the liquor being returned to the bath for further treatment.

Instead of zinc, other metals, if amalgamated, may be used as the negative electrodes.—E. T.

An Improved Method of Manufacturing Woven Plates for Secondary Batteries. M. Bailey and I. Warner, London. Eng. Pat. 2368, February 16, 1888. 8d.

THESE plates consist of lead strips or wires interwoven, preferably at right angles, with threads or strands of cotton, twine, silica cotton, or spun asbestos fibre, and are formed according to the Planté method.—B. T.

Improvements in Secondary Batteries. W. Kingsland, London. Eng. Pat. 3223, March 2, 1888. 6d.

THE inventor's object is to produce an accumulator which, by absence of local action, may remain in working condition for a considerable time, and so be used for electric bells, telegraph working, &c. An electrode is employed, therefore, consisting mainly of dense peroxide of lead, not in contact with any oxidisable materials. These electrodes are preferably made in accordance with Eng. Pat. 5867 of 1887. (This Journal, 1888, 328.)

For the other electrode the patentee employs amalgamated zinc, or a deposit of pure zinc on some such metal as lead. The electrolyte is preferably dilute sulphuric acid, and the cell may be sealed if desired.—E. T.

Improvements in the Elements for Secondary Batteries. J. A. Timmis, London. Eng. Pat. 10,064, July 21, 1888. 6d.

In order to cheapen, lessen the weight, and perfect the action of the positive elements or cathodes, they are made of litharge combined with a suitable solution, preferably sulphate of ammonia, supports of lead or an inoxidisable material being used.—B. T.

An Improved Apparatus for Pickling or Cleaning the Surface of Iron and other Metals to Prepare the same for Coating with Tin or other Metal. A. Gutensohn and J. M. James, Old Ford. Eng. Pat. 16,848, November 20, 1888. 6d.

THIS is an improvement on Eng. Pat. 8324 of 1886 (this Journal, 1887, 517), and is intended to obviate the gradual slowing off of the pickling process noticeable in the arrangement previously employed. The method is an electrical one, and the apparatus is constructed in a similar manner to and on the principle of the ordinary secondary battery. The bath is made water-tight and of wood or some other non-conducting material. It is divided off into several compartments by means of non-conducting partitions which fit into grooves in the sides of the bath. These partitions do not quite reach to the top of the sides of the bath, so that when the pickling solution (which may be either acid or alkaline) is run into the bath they are submerged. On the inner side of one end of the bath, and on the corresponding side of each partition, are fixed sheets of metal (preferably lead) which, however, do not reach to the bottom. Two strips of non-conducting material are fixed to the bottom of the bath so that their ends touch the partitions. The upper surface of these strips is faced with metal (preferably lead strips). Alternate strips on the bottom of each compartment are connected with the metal sheet on the side of the next compartment by means of an insulated wire. The current enters by a conductor which is attached to the end plate, and is led away by an insulated wire connected with one of the strips in the last compartment. The desired number of plates to be pickled are placed in the compartments so that their lower edges touch the strips on the bottom. To prevent their touching the vertical sheets, these latter are protected by vertical non-conducting laths which are fixed over them. The iron plates thus form part of one pole and the sheets the other poles. The sheets and strips may similarly be fitted to a crate and the latter can then be immersed in a bath. If other shaped pieces or articles of iron are to be cleaned, the shape of the bath and of the compartments has to be altered accordingly.—F. W. T. K.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

On the Production of Machine Oils, Vaseline, &c. from Mineral Oils. Chem. Zeit. 12, 1727.

THE oils which are to be purified have first to be dried, either by letting the water settle or by means of calcium chloride, sodium chloride, or sometimes by small quantities of glycerin, according to the nature of the oil; the oil, thus perfectly dried, is brought into an iron cylinder, which is coated inside with lead, and forms a cone at the lower end, at the lowest point of which is a tap. The oil is at first mixed, by means of compressed air, with 2 per cent. of sulphuric acid of 66° B. After mixing for two hours the air is shut off and the liquid allowed to settle for three hours. Then the acid is run off, the last traces being removed after another half hour. This treatment is repeated with 8 per cent. of sulphuric acid of 66° B. for four hours, or so long as sulphurous acid escapes. The sulphuric acid has to be gradually added, in intervals of half an hour. The whole operation is repeated with 10 per cent. of acid. Special care has to be taken that the oil does not get warm; in such a case the addition of sulphuric acid must be stopped until the mass is again cool. It may be advisable to add to the last charge of acid $\frac{1}{2}$ per cent. of dry zinc chloride. The oil is pumped, after all acid has been removed, into a second vessel of similar shape, and 20 per cent. of warm water is added, but without mixing it with the oil. After one hour's standing the water is removed and the operation repeated. The oil is now mixed by compressed air twice with 15 per cent. of warm water till no longer acid, and finally with 5 per cent. of caustic soda of 6°—8° B.

Very thick oils are mixed with petroleum naphtha. The mixing with sulphuric acid has, of course, to be done in such case in closed vessels. After the purification the naphtha is removed by distillation with superheated steam.

Tar oils containing creosote require a preparation with dilute caustic soda. Steaming very often removes from the oils any remaining odour. Treatment of the perfectly dry oil with animal charcoal has a more or less bleaching effect.

—A. L.

Olive Oil. K. Hazura and A. Grüssner. Monatsh. Chem. 9, 944—946. (Compare this Journal 1888, 506—507 and 680—682.)

OLIVE oil is generally considered to contain 72 per cent. of tri-olein and 28 per cent. of palmitin, stearin, and arachidin, but the iodine equivalent of the oil, as determined by Hübl's reagent, is higher than that accounted for by the olein contained (83 instead of 62.1), whence it is probable that either a lower acid of the oleic series or a more unsaturated acid than oleic acid, having a minimum iodine equivalent of 90.1, is present. In order to ascertain the presence of such an acid, the authors saponified pure olive oil (iodine equivalent 83) with caustic potash of sp. gr. 1.27, and then oxidised the aqueous solution of the potassium salts obtained with a $\frac{1}{2}$ per cent. solution of potassium permanganate. The oxidation was stopped after 10 minutes by the addition of an excess of sulphurous acid, and the separated acids dried on a porous plate, and extracted with ether. The residue from the ethereal extract consisted of a thick oil, and probably contained the unoxidised portion of the oil, together with lower fatty acids and azelaic acid. The portion insoluble in ether, which amounted to 80 per cent. of the weight of olive oil taken, was extracted with water, when a small portion (4 per cent. on the original weight of oil) dissolved, which crystallised out on cooling in crystals, melting at 162°, and which gave numbers on analysis agreeing well with the formula $C_{18}H_{36}O_6$. The acid is, therefore, sativic acid. The portion insoluble in

water proved to be dihydroxystearic acid; it crystallised from alcohol in microscopic tablets, and melted at 136°—137°. Sativic acid is tetra-hydroxystearic acid, $C_{18}H_{32}O_8(OH)_4$, and the fact that it is obtained together with dihydroxystearic acid by the oxidation of olive oil, points to the presence of a second acid in the oil, having the formula $C_{18}H_{32}O_2$; this is linolic acid (stearoleic acid), and judging from the relative quantities of the two acids obtained in the oxidation, the olive oil will contain about 7 per cent. of linolic acid to 93 per cent. of oleic acid.

The authors are of opinion that most of the non-drying oils contain linolic acid as well as oleic acid, and have proved this to be the case with earth-nut oil. They are engaged in examining other oils from this standpoint.

—C. A. K.

Uculuba Fat. E. Valenta. Zeits. f. angew. Chem. 1889, 3.

THIS fat, according to Schädler, obtained from the seeds of *Myristica beenhiba*, Humb., and according to Tschirch, from those of *M. Surinamensis*, is of a deep brown colour, and is tolerably firm; it possesses a peculiar aromatic odour, due to the ethereal oils it contains. On heating to 39° it melts, and at higher temperatures it possesses a somewhat disagreeable acid smell. Treatment with steam removes the ethereal oil and small quantities of volatile acids.

A sample, after treatment with steam, contained 93.4 per cent. of total fatty acids, 8.8 per cent. of free fatty acids. A quantity of the fat was saponified, and the soap decomposed with sulphuric acid. The fatty acids so obtained melted at 46°, and possessed a saponification equivalent of 219—220, and an iodine equivalent of 9.5. Treated with hot alcohol of 96 per cent., and after a time filtered, they left a resinous mass, having somewhat the odour of Peru balsam.

The crystals which separated from the clear liquid melted at 53°—53.5°, their saponification equivalent was 245—245.4, and their iodine equivalent 0. They thus consisted of myristic acid. Fractional precipitation with magnesium acetate showed that no other acid was present, with the exception of oleic acid. From the iodine equivalent the author concludes that the fatty acids consist of 89.46 per cent. of myristic acid and 10.54 per cent. of oleic acid.

This is, at all events, favourable to the use of the fat for making candles.—T. L. B.

The Rancidity of Fats. M. Gröger. Zeits. f. angew. Chem. 1889, 62—64.

THE tendency of fats to develop free fatty acids by keeping, and thereby to acquire a rancid smell, due to the volatility of a portion of these, is well known (for facts pointing to some other cause for rancidity, see this Journal, 1889, 54), but no precise knowledge exists as to the conditions governing this change.

The author accordingly investigated it in the case of six kinds of fat, viz., tallow, cocoa-nut oil, palm oil, cotton-seed oil, olive-kernel oil, and bone fat, in the following way: A portion of the clarified fat was placed in a flask of about 50 cc. capacity, which was then securely closed; another part was mixed with 4 per cent. of a concentrated solution of albumen (white of egg), and similarly secured; a third was soaked up by strips of dry filter-paper, previously extracted with water and ether, pleated and placed in large glass dishes, allowing free access of air; a fourth was similarly dealt with, save that the filter-paper was first saturated with a 10 per cent. solution of albumen, and dried. After the lapse of four years, the percentages of free fatty acid in all the samples were determined, and compared with their values before treatment. In the case of the fats enclosed in flasks, the portion for analysis could, of course, be taken direct; while in that of the strips of filter-paper, the plan adopted was to exhaust them with ether, evaporate the ethereal solution to dryness, and wash the residue repeatedly with boiling water, leaving a mixture of neutral fat and insoluble fatty acids which could be titrated in the ordinary way.

The results thus obtained are recorded in the following table :—

Percentage of Free Fatty Acid.

Kind of Fat.	Original.	After four Years.			
		With Exclusion of Air.		With Exposure to Air.	
		Alone.	In presence of Albumen.	Alone.	In presence of Albumen.
Cotton-seed oil.	0.33	0.36	0.52	39.34	39.18
Cocoa-nut oil...	2.51	5.34	4.75	5.45	5.88
Tallow.....	4.49	7.02	8.99	21.82	16.73
Bone fat	51.26	51.57	61.79	49.93	53.95
Palm oil	71.86	84.03	85.67	69.20	65.31
Olive-kernel oil	71.99	71.18	71.64	54.32	56.75

From this it appears that, with the exception of palm oil, the fats by themselves suffer little change if air be excluded; the presence of albumen somewhat favours the formation of free fatty acid, though only in the case of bone fat is the increase considerable. Exposure to air causes an increase in the first three, but with the remainder a decrease occurs; this is probably due to the formation of products volatile, or soluble in water. On the whole, the presence of albumen seems to hinder the change, possibly because of the diminished porosity of the paper saturated with it. One thing is plain however, viz., that the presence of air is the most important condition in the production of rancidity.

The mean combining weights of the fatty acids (free and combined) isolated from the ethereal extract of the filter-paper saturated with the fats under investigation (without the addition of albumen) were determined, and found to be, without exception, lower than those for the fats before exposure. This points to the splitting up of the fatty acids, during the period for which they were exposed, into simpler oxidation products, instead of their undergoing change by mere additive absorption of oxygen. Further evidence in this direction was afforded by the isolation of azelaic acid ($C_9H_{16}O_4$) mixed with a little suberic acid ($C_8H_{14}O_4$) from that portion of the rancid fats that was soluble in water. No free glycerol appeared to be present, and therefore the author concludes that it must suffer oxidation as well as the fatty acids.—B. B.

PATENTS.

Improvements in the Purification of Cotton-seed Oil, and in Apparatus therefor. R. Hunt, Liverpool. Eng. Pat. 550, January 13, 1888. 6d.

NEITHER drawings nor detailed explanations are given, but the patentee claims the use of "high speed minutely acting mixing apparatus" for promoting the action of the alkaline purifying agent upon the oil, and of centrifugal separators for removing the soap formed in the process, such as a hydro-extractor with the basket unperforated. The purifying solution and the oil are employed in approximately equal bulks, and at temperatures between 100° and 120° F.—W. L. C.

A Process for the Manufacture of a Soap soluble in Sea-water. O. H. von Wilke, Charlottenberg, Germany. Eng. Pat. 2306, February 15, 1888. 6d.

"EXPERIMENTS have proved that the separation of soap from its solution does not follow from the addition of dissolved borate of potash through solutions of common salt the strength of which corresponds to or exceeds that

of sea-water." Hence the patentee incorporates with hard commercial soaps about 0.2 per cent. of the potassium salt of boracic acid.—W. L. C.

A Composition for Cleaning Wall Papers, Papered Ceilings, and the like. E. Johnson, London. Eng. Pat. 2650, February 22, 1888. 4d.

FLOUR, bran, fuller's earth, and "Sanitas" powder are incorporated with each other, and with as much water as will bring the mass to the consistency of soft india-rubber.—W. L. C.

An Improved Compound for Washing and Laundry purposes. W. T. Lawson, Manchester. Eng. Pat. 2971, February 28, 1888. 4d.

PARAFFIN oil is incorporated with what is essentially a vegetable oil soap mixed with silicate of potash.—W. L. C.

Improved Preparation for Cleansing purposes. L. Grave, London. Eng. Pat. 13,673, September 21, 1888. 6d.

THE bark of any tree of the Sapindus family (e.g., Saponaria) is extracted with water, or the powdered bark is mixed with mucilage, oils, &c. to form a tablet or block as a substitute for soap.—W. L. C.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

Red Lead. R. Frühling. Zeits. f. angew. Chem. 1889, 67-68.

THE many purposes for which red lead is used fall naturally into two classes; in the first, comprising its employment for joint-making, and as a pigment, purity is not essential, while in the other, covering such uses as in pharmacy and glass-making, it is imperative. The commonest adulterants met with are insoluble substances such as barium sulphate, clay, and brickdust, which are found to the extent of even 10 per cent. in so-called "best" red lead.

The following table shows the proportion of insoluble matter present in various commercial samples:—

Number of Sample.	Percentage.
1	7.75
2	27.19
3	9.59
4	8.46
5	25.39
6	17.66
7	9.60
8	2.08
9 (from a druggist's)	1.25

THE wholesale price is found to decrease with the increase in impurity, but not proportionately, while the retail price is much the same for all qualities. Of the samples in the table, Nos. 1, 3, 4, 7, 8, 9, contained fine sand and clay, while in Nos. 2, 5, 6, barium sulphate was present; the first-named impurities may have been derived from the use of inferior raw material, or carelessness in manufacture, but the last is evidently an intentional addition.—B. B.

PATENTS.

Improvements in and connected with Varnishes. F. Crane, London. From W. D. Field, Short Hills, U.S.A. Eng. Pat. 15,771, November 17, 1887. 6d.

THIS inventor uses a solution of cleared, purified, and bleached shellac, prepared according to Eng. Pat. 15,772 of 1887 (following abstract), in combination with a solution of pyroxilin in a practically non-hygroscopic menstruum miscible with the shellac solution.—E. G. C.

Process for Purifying and Clarifying Shellac or Solutions of Shellac. F. Crane, London. From W. D. Field, Short Hills, U.S.A. Eng. Pat. 15,772, November 17, 1887. 6d.

THE shellac is dissolved in methyl-alcohol, benzine added, and the mixture agitated. The benzine is drawn off, and a clear solution of shellac left in the vessel.—E. G. C.

Improvements in Dyeing and otherwise Treating India-rubber and India-rubber Compositions, Farina, Starch, and French Chalk, and Fabrics producing a Bronzed appearance. J. F. Kelly, London. Eng. Pat. 17,260, December 15, 1887. 6d.

THE inventor dissolves "aniline dyes in a strong solution of alcohol spirits, wood naphtha, nitric acid, and turpentine spirits," and passes the fabric over a roller partly immersed in a trough containing this solution: a bronzed appearance is thus produced on fabrics coated with india-rubber and compositions containing india-rubber. To dye india-rubber goods and compositions containing india-rubber, farina, starch, and French chalk, the quantity of nitric acid is reduced.—E. G. C.

Improvements in Forming Solutions and Compounds of Nitro-Cellulose. A. Orr, Glasgow. Eng. Pat. 487, January 12, 1888. 6d.

THE solvent employed is "a chlor-acetate of chlor-amyl," prepared by the action of chlorine on fusel oil "and other chemicals," and may be diluted with from 2—5 parts of fusel oil. A solution of nitro-cellulose in this solvent mixed with castor-oil and "wood pitch" is said to give, by suitable treatment, a very good insulating material.

—E. G. C.

Improved Process for Fired Painting on Metal Plates. C. J. Leroux and J. H. Fischbach, Paris, France. Eng. Pat. 12,892, September 6, 1888. 6d.

THE metal plate is fixed to a piece of canvas by rye-flour paste; when dry it is cleaned with "essence of turpentine," and the desired colours, mixed with turpentine and varnish, put on; the whole fired at 50°—100° C. and the painting and firing repeated until the desired effect is obtained, when it is varnished and again fired.

When used for mural decoration these plates can be fastened to the wall with a mixture of rye-paste and Flemish glue, if it be dry, or with one of white lead, linseed oil, and turpentine if it be damp.

The process can also be used for preparing letters for signs.—B. B.

Improvements relating to the Manufacture of Lead Pigments, and to Apparatus therefor. J. W. Hall, Bristol. From G. T. Lewis, Philadelphia, U.S.A. Eng. Pat. 14,107, October 1, 1888. 6d.

A ELAST of intimately admixed gas or liquid hydrocarbon, air, and finely-divided galena, is introduced into a combustion chamber, and inflamed at the entrance thereof. The resultant salts are forced into receptacles of textile fabric.

—E. G. C.

Improvements in the Manufacture of Paint. A. J. Boulton, London. From C. H. Eichler, Dresden, Germany. Eng. Pat. 15,997, November 5, 1888. 4d.

THE constituents used are:—pulverised slate, 50 per cent.; oil tar, 40 per cent.; sicative, 4 per cent.; sal-ammoniac,

3 per cent.; water-glass or siliceous varnish, 3 per cent. Paint so prepared is said to protect wood and other material against weather, fire, and rot.—E. G. C.

Improvements in Vulcanised Plastic Compounds. A. J. Boulton, London. From W. Kiel, New Jersey, U.S.A. Eng. Pat. 17,679, December 4, 1888. 6d.

INDIA-RUBBER, sulphur, punice stone, oil, and beeswax in proportions varying with the use to which the product is to be put, are thoroughly incorporated, moulded into any desired form, and vulcanised for 10—14 hours at a pressure of 50—60 lbs. The articles thus made are said to answer the purposes of hard rubber, while being stronger, cheaper, and easier to manufacture. The punice stone is regarded as an essential and novel ingredient.—B. B.

Improvements in Filling for use by Painters and others. S. Downs and W. Greenwood, Leeds. Eng. Pat. 17,799, December 6, 1888. 4d.

EQUAL parts by weight of "lead" and "patent driers" are mixed with equal parts by measure of japaners' gold size and turpentine, the whole made into a stiff paste by the addition of pounded "whitening" (preferably previously heated), and the resulting mixture applied to the surface to be treated with a knife or spatula.—B. B.

XV.—AGRICULTURE, MANURES, Etc.

Rare Constituents of Beet-root Ash. E. O. von Lippmann. Ber. 21, 3492—3493.

THE author finds boric acid in the roots and leaves of the beet. Vanadium is also found in the carbonaceous residue after distillation of the molasses. Among other elements manganese, caesium, and copper are occasionally found.

—J. B. C.

Cultivation Experiments with Different Varieties of Potatoes on Light Sandy Soil. Vibraus. Zeits. f. Spiritus Ind. 1888, 80.

THE land was in good agricultural condition; the potatoes were sown by drill in May and subsequently cultivated in the usual manner. The weather, at first fine and warm, became cold and dry towards the end of summer. The plants grew well, with the following results:—

Variety.	Condition on 1st September.	Yield.	
		Centners of Tubers.	Starch per Cent.
Imperator	Drooping slightly	130·0	19·2
Odin	Drooping very much	102·5	17·9
Sutton's Magnum ? Bonum	(Leaves half yellow with spots	8·5	18·4
Matador	Slightly drooping	102·5	14·1
Hortensia	Leaves completely yellow ..	87·5	15·4
Reichskansler	Leaves mostly dark green with few spots and few yellow leaves	62·5	21·4
Rosalie	Yellow and spotted	78·75	16·6
Juno	Almost entirely yellow and spotted	52·5	16·5

THE "Imperator" potatoes are the best for dry, especially sandy soils, for they not only yield well but the tubers are of good quality and keep well; this is not the case when they are grown on wet soils. The percentage of starch in potatoes of 1887 was from 2 to 4 per cent. lower than in 1886, owing to drought and cold.—D. A. L.

Destruction of Moss by Ferrous Sulphate. P. M. Delacharlonny. J. de l'Agricult. 1888, 737—739. L. Destreux. *Ibid.* 747.

THE former author concludes from numerous experiments that properly applied to meadow-land ferrous sulphate destroys moss and so facilitates the development of grasses. It is best applied in March, but may be sown later, even in autumn, without acting injuriously; the quantities employed vary with the condition of the meadow, when new 300 kilos. per hectare is sufficient, 600 should be used on old pastures, and 2,000 when the moss is very (8—10 cm.) thick. The sulphate may be used solid or in solution. The latter author has made observations which confirm the above.

—D. A. L.

Action of Ferrous Sulphate on Different Soils. P. M. Delacharlonny. Jour. de l'Agricult. 1888, 787—790.

IN the author's experiments various soils were analysed, and subsequently crops of wheat, lucerne, and potatoes were grown on them, with and without dressings of ferrous sulphate. The results indicate that ferrous sulphate is beneficial to these crops, being more so when the soil is poor in iron, as will be seen from the following data. On meadow-land the following results in kilos. per hectare were obtained:—

Percentage of Iron Oxide in Soil.	Yield without Ferrous Sulphate.	Yield with Ferrous Sulphate.	Quantity of Ferrous Sulphate used.
2.920	2,000	4,785	65
2.531	1,838	3,952	350
1.340	1,807	2,864	200
3.573	4,316	1,663	200
4.321	3,614	3,500	125

With lucerne the crop was increased 25 per cent. by dressing with ferrous sulphate, although the soil already contained 4.32 per cent. of ferric oxide, whilst the potato crop was also much benefited by the application of ferrous sulphate on a soil poor in iron; lime manuring also produced a good effect, as that constituent was also deficient in this soil.—D. A. L.

Value of the Nitrogen in Chili Saltpetre and Ammonium Sulphate for Potatoes and Oats. Baessler. Wochenbl. d. pommerseh. akons. Gesell. 1888, 163—164, 270—271.

POTATOES were grown on a sandy soil of the following composition, with superphosphate and with varying quantities of nitrogen, in some cases as Chili saltpetre, in others as ammonium sulphate or a mixture of the two salts. The dry soil contained per cent.: water, 1.18; organic matter, 5.36 (containing nitrogen, 0.21); ash, 93.46; insoluble in hot HCl, 88.02; Fe_2O_3 and Al_2O_3 , 2.32; CaO, 1.23; MgO, 1.33; K_2O , 0.11; P_2O_5 , 0.30. The mean results obtained were, numbers being kilos. per hectare:—

Manuring.	Yield.
Without manure	10,213
100 of Chili saltpetre	11,569
200 " 	11,867
75 of ammonium sulphate	10,250
100 " 	10,475
150 " 	10,800
200 " 	11,575
37.5 of ammonium sulphate, 50 of Chili saltpetre	10,577
50 " 50 " 	10,530

IN no instance did the ammonium sulphate cover its cost by the increase of crop produced by it; the nitrate, on the other hand, was remunerative in small quantities.

Ammonium sulphate proved better with oats on a humous sandy soil which had received a dressing of superphosphate, the results being as follows, numbers as before:—

Manuring.	Yield.	
	Straw and Chaff.	Grain.
Unmanured	2,812	1,562
100 of Chili saltpetre	4,127	2,631
200 " 	4,700	2,517
75 of ammonium sulphate	3,883	2,692
150 " 	4,160	2,473
37.5 " 	3,720	2,618
50 of Chili saltpetre		

The beneficial action of the ammonium sulphate is attributed to the wetness of the season.

In both series of experiments the saltpetre contained 16 per cent. of nitrogen, the ammonium sulphate 20.1 per cent.—D. A. L.

Experimental Cultivations with German and Russian Reproductions of the Sugar Beet (Fimbrin blanche améliorée). F. Kudełka. Deutsche Zucker-Ind. 1888, 423—424.

IN Germany the plants for seed are grown with artificial manures, but in Russia this is not the case. Three samples of Russian seed and two of German were all cultivated in five different places: four of these soils were deep black earth, and had grown wheat or buckwheat as previous crops, the fifth soil had grown clover. In all cases the beet were drilled in rows 14 inches apart, and the plants 10 inches from one another. The crops obtained from the Russian seed were nearly as good as those from the German seed.

—D. A. L.

Dry-decay of Potato Stems. P. Sorauer. Oesterr. landw. Wochenbl. 1888, 264.

THE author draws attention to a comparatively new and little known potato disease. When attacked by "wet-rot" potato stems become brown, the leaves black, and the plant putrid, whereas in the new disease individual stalks and tubers sicken, in the midst of healthy ones, on the same plant, the former becoming dry and decayed. It originates from a fungus hailing from the uppermost layers of the soil; the stems are attacked at a point in contact with the soil, and the disease spreads upwards and downwards, intercepting the sap and preventing its upward progress with consequent starvation of the affected stem. If the roots or tubers be attacked all further green growth ceases. Luxuriant haulms and loose cell tissues are favourable for the penetration of the fungus into the rind of the stem. In wet weather white warts appear on the stems; these loosen the cell tissue and prepare the way for the fungus. Increased aeration is the natural means of combating this fungus, and when practicable the potatoes should be pulled.—D. A. L.

On the Soils of Algeria. A. Ladureau. Compt. Rend. 107, 1154—1155.

AFTER a course of travels in Algeria for the purpose of examining the composition of the soils, the author concludes that the inferiority of cereal crops in the colony is due to insufficiency of phosphoric acid in the soil. The following figures in grms. per kilo. of dry earth are indicative of the

result of numerous careful estimations which were made in duplicate.

	Highest.	Lowest	Mean.
Department of Alger	1.97	0.26	0.76
„ „ Oran	1.37	0.23	0.54
„ „ Constantine ..	1.25	0.30	0.69
General average for Algeria ..	0.68		..

—G. H. B.

XVI.—SUGAR, STARCH, GUM, Etc.

The Constitution of Sorbinose. H. Kiliani and C. Scheibler. Ber. 21, 3276—3281.

SORBINOSE, like levulose, is inactivated upon when treated with bromine and water at the ordinary temperature; hence it does not contain the aldehyde group. With hydrocyanic acid, sorbinose combines readily, but the compound could not be obtained in a crystalline form, and it decomposes very readily into its components. Oxidised with nitric acid (sp. gr. 1.39) at 35 for 40 hours, a small quantity of a dibasic acid results; this acid possesses no reducing properties, and, therefore, contains neither a ketone group nor two hydroxyl groups attached to one carbon atom. An analysis of the potassium salt of the acid agrees with the formula $C_8H_6K_2O_7$, and the crystalline form of this salt is identical with that of the potassium salt of trihydroxyglutaric acid obtained by Kiliani as an oxidation product of arabinose (Ber. 21, 3006). The constitutional formula of this acid is $CO.OH(CH.OH)_3.CO.OH$, and hence sorbinose is a ketone alcohol of the formula—

Dessaigues previously obtained a dibasic acid ($C_8H_6O_7$), called by him aposorbic acid, by the oxidation of sorbinose with nitric acid. Its melting point (110°) differs from that of the acid obtained by the authors (127°). Sodium amalgam acts on sorbinose, forming an amorphous product; with red phosphorus and hydriodic acid a hexyl iodide results.—C. A. K.

The Pectins of the Sugar Beet. J. Weisberg. Chem. Zeit. 13, 2.

UNDER this heading reference was made in the Chem. Zeit. Rep. 1888, 335, to a communication by the author which appeared in *La Sucrerie Belge*, 1888, 17, 109, in which he believes to have shown that the dextro-rotary substances extracted by water from beets previously exhausted by alcohol, give on hydrolysis, as chief product, arabinose. On this formation of arabinose, the author based his views as to the nature of these bodies extracted by water. In the present communication, the author brings forward further arguments to prove the correctness of his conclusions. Although unable to separate the arabinose in a state of purity, the author considers its formation to be sufficiently proved by means of the special reactions mentioned in the original memoir.

When exhausted beets are boiled with milk of lime, levo-rotary calcium metapectate (arabinates) is obtained; this was first shown to be the case by Scheibler. Metapectic acid when boiled with sulphuric acid yields chiefly arabinose, which was also proved by Scheibler. Beets previously exhausted with alcohol, when simply heated with water, yield at first a neutral solution, which gradually becomes acid. On boiling this with milk of lime for a considerable period, a portion of the dissolved dextro-rotary substance is precipitated, the rest remaining in solution as calcium salt. This solution is levo-rotary, and contains calcium metapectate, i.e., the calcium salt of the acid which must

give arabinose on hydrolysis. This metapectic acid, however, can only have been formed from bodies of the same class. These are pectin and metapectin, which dissolve when exhausted beets are treated with water, and as such, are completely precipitated by milk of lime and basic acetate of lead. On prolonged heating they are converted into metapectic acid, which is not precipitated by basic acetate of lead in excess, and after filtration the solution is slightly levo-rotary.

On these grounds it follows that the views put forward by the author, as regards the nature of the dextro-rotary substances contained in exhausted beets, are correct.

—H. T. P.

PATENT.

Improvements in or relating to the Manufacture or Purification of Gums and Gum Resins. W. H. Stead, Liverpool. Eng. Pat. 245, January 6, 1888. 6d.

Dextrine, or some other cheap adhesive material, is dissolved in sufficient water to form a not too viscous liquid, shaken up with, or filtered through, animal charcoal or similar clarifying material, and concentrated to a suitable consistency either at the atmospheric pressure or in a vacuum pan; the charcoal is preferably dried by exposure to a temperature of about $300^\circ F$. immediately before use. The gum may be rendered transparent by the addition of a little nitric acid.

It is claimed that the product is free from offensive taste and smell, while its adhesiveness is unimpaired.—B. B.

XVII.—BREWING, WINES, SPIRITS, Etc.

Copper in Wine. Frühauf and Ursié. Le Staz. Speriment. Agr. Ital. 1888, 704. Sestini and Tobler. *Ibid.* 379.

WINES obtained from vines which have been treated with copper salts to prevent attacks of the peronospora contain, according to Frühauf and Ursié, at the most 0.25 to 0.28 mgrm., and at the least 0.01 to 0.02 mgrm. per litre; in only one instance did they find such a wine free from copper. In these determinations the copper was separated electrolytically. Sestini and Tobler point out that such wine does not contain more than 0.25 mgrm. of copper per litre, and is, therefore, harmless even if consumed every day.

—D. A. L.

PATENTS.

Improvements relating to the Treatment of Beer Wort, and to Apparatus therefor. C. Hoffmann and L. Ebert, Thuringen, Germany. Eng. Pat. 2059, February 19, 1888. 8d.

This invention relates to apparatus for sterilising and cooling beer wort, whereby it is kept completely protected from any injurious action of the micro-organisms of the air during the whole cooling process, from the time it leaves the copper until it enters the fermenting vat.

The apparatus consists of (A) a wort sterilising and filtering vessel in combination with (B), a circular wort refrigerator enclosed in a casing which can be hermetically closed, and also with (C) an air-cooling, drying, and filtering apparatus.

The wort after boiling in the copper is run direct, hops and all, into the sterilising vessel containing only sterilised air; here it is again boiled for a short time, and left to rest for about an hour so as to allow the hops to settle out at the bottom of the vessel, and serve as a filtering medium for the supernatant liquor; from here it is run into the cooling vessel, sterilised air under pressure at the same time being introduced. The wort by this means becoming thoroughly

aerated and cooled to the necessary degree, is run free from turbidity and micro-organisms into the fermenting vessels. Descriptive drawings of the apparatus are given.—J. H.

Improvements in the Manufacture of Brewers' Finings, and in Machinery and Apparatus therefor. E. Thatcher, Nailsea. Eng. Pat. 3193, March 2, 1888. 8d.

According to this invention, the isinglass or other material from which the finings are extracted is, with the proper quantity of water, placed in a barrel or tub. In this is immersed a perforated cylindrical vessel, to which rotary motion is imparted, the vessel being supported in a frame, which is clamped or otherwise secured to the barrel or tub. Through orifices in the cover of the cylindrical vessel the contents of the barrel are admitted thereto, and as the vessel rotates the contents are expelled by centrifugal force through the perforations in the sides. The finings are thus strained in passing out of the cylindrical vessel back into the barrel or tub.—J. H.

An Improvement in Brewing. B. W. Valentin, Birmingham. Eng. Pat. 3754, March 10, 1888. 4d.

When wort is drawn off from the mash tun it holds in solution certain nitrogenous substances, which, under some circumstances, tend to make the finished beer turbid. This invention relates to a simple means of preventing this, by getting rid of the objectionable portions of such nitrogenous substances in the following manner: the whole of the wort is drawn off from the mash tun, and heated to 180° F.; by this means a change is effected in the nitrogenous matter, such that when the wort is again cooled to 150° F., this matter becomes separable from the wort, which is then passed through the grains from which it was obtained. These, acting as a filter, allow the pure wort to pass through, but retain the most objectionable of the nitrogenous substances.—J. H.

Improvements in the Manufacture of Saccharine Liquors for Brewing and other Purposes. J. Grass, G. C. Heilmann, and O. Olme, London. Eng. Pat. 13,531, September 19, 1888. 4d.

This invention consists in the manufacture of ordinary glucose from rice, maize, sago, &c., the sulphuric acid usually employed being replaced by nitric acid in similar proportions (2 per cent.). As soon as the conversion is complete, the nitric acid is removed by the addition of a certain quantity of "disulphide of lime," the mass then boiled for 15 minutes, and neutralised by carbonate of lime, when every trace of nitric acid is said to be removed. It is claimed that a purer and cheaper production results from this process, containing "neither dextrin nor other impurity."—J. H.

Improved Filtering Apparatus. H. H. Leigh, London. From B. E. Gasquet and H. E. Gaulne, Bordeaux, France. Eng. Pat. 13,625, September 20, 1888. 8d.

This apparatus, adapted to the filtration of wines, &c., consists of filtering cloths placed between corrugated metallic gratings, and held apart by perforated rings, the said cloths, gratings, and rings being built upon layers about a central cylinder consisting of a perforated and winged chamber.—E. G. C.

Improvements in Apparatus for the Manufacture of Malt. H. H. Lake, London. From J. W. Tree, Boston, U.S.A. Eng. Pat. 16,885, November 20, 1888. 1s. 1d.

This invention relates to a malt-growing and drying apparatus having a series of stirring buckets or rotary lifting devices arranged upon a horizontal shaft carried parallel to the floor, upon which the grain or malt rests, and which stirring buckets may be varied as to the degree or extent of their lifting capacity. The invention further relates to the

employment of a scraper for removing the malt from the malting floor through a trap door in the floor, and to various details of organisation and construction, all of which are fully illustrated by means of several drawings.

"The operation of the machine is as follows:—The grain or malt is introduced into the malting chamber, which is cylindrical in shape, covering the floor thereof to the depth of a number of inches, and when desired for the purpose of assisting in the malting process, the mass of grain or malt is stirred, broken up, and separated by the movement of the buckets through the mass; the buckets advancing in a line and rotating lift the grain or malt from the floor of the chamber in comparatively small quantities, and by lifting blades which deposit in a broken, separate condition, and in a new relation to the rest of the malt, and to the floor of the machine."

"This changing of the mass continues as long as may be desired," and "may be used in connexion with all the various stages of the treatment of the grain."

The apparatus can also be applied to an oblong floor by altering its construction somewhat.—J. H.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A)—CHEMISTRY OF FOOD.

PATENTS.

An Improved Method of Preparing Ferment of Rennet. F. Graeff, Alkmaar, Holland. Eng. Pat. 16,652, December 3, 1887. 4d.

"A pure and clear solution of the ferment, not containing above 10 per cent. of table salt, is evaporated to dryness in vacuo at a temperature not exceeding 40° C. The residue is reduced to powder, which is thereupon washed with concentrated solution of table salt in view of removing the colouring matter present." The product is dried again and mixed "with an innocuous soluble salt—for instance, with table salt."—E. G. C.

An Improved Process of Preserving Eggs. H. H. Lake, London. From F. Tiedemann, Copenhagen, Denmark. Eng. Pat. 1653, February 3, 1888. 8d.

Carbon dioxide, dried by calcium chloride and sulphuric acid, is introduced into the receptacle containing the eggs. The carbon dioxide is said to penetrate through the pores in the shell of the eggs, and when the eggs are removed keeps the eggs fresh.—E. G. C.

Apparatus to be Employed in Effecting the Preservation of Fruit, Vegetables, Meat, Fish, and other Perishable Articles of Food. W. Peacock, South Melbourne, Australia. Eng. Pat. 2426, February 17, 1888. 8d.

The apparatus described is intended to carry into effect the process of preserving perishable articles of food described in Eng. Pat. 11,233 of 1885. (This Journal, 1886, 104.)

A is a leaden vessel in which sulphur is burned for the production of sulphurous acid; C a cooling worm immersed in water in tank D; G is the receptacle for the fruit or other material, into the lower part of which the sulphurous acid is conducted by flexible pipes E; H is a pipe sealed by the rubber-flap I, passing from G to an exhaustor K, which, when the apparatus is in work, removes the air from G and draws in the sulphurous acid formed in A.

—C. C. H.

An Improved Process for Manufacturing Conserved Meats.

H. Stachelhaus, Ruhrort-on-Rhine, Germany. Eng. Pat. 16,335, November 10, 1888. 4d.

THE object of the inventor is the production of a preserved meat in which the meat fibre, jelly, and fat are all present in their normal proportions and without separation. Meat from an animal recently slaughtered and still warm is beaten thoroughly until pliable, minced finely, and allowed to cool for two days at a temperature of 5° to 8° C. It is again minced, mixed intimately with any other flesh similarly treated,—e.g., beef may be mixed with pork,—put into tins, hermetically sealed, and immersed in a water-bath having a temperature of 87° to 93° C. Thus prepared the meat retains its normal proportions of fibre, jelly, and fat.

—C. C. H.

(B)—SANITARY CHEMISTRY.

The Supply of Water from Wells, and its Hygienic Aspect. F. Hueppe. Journ. f. Gasbel. 1889, 15—23.

UNTIL quite recently, when examining a water for hygienic purposes, it has been the custom to ask: Is the water deleterious to health, and how may its impurity be detected?

from the prevention standpoint only. This plan demands a water supply and a method of distribution which absolutely negatives pollution or infection at any stage. Underground water is the best on all accounts, since Nature provides for its purification and disinfection. To obtain a pure supply the well should be built in a proper manner, and the author indicates the following plan of construction:—(1.) The ground surrounding the well should be paved, and should slope gently downwards on all sides, so that all dirty water, &c. may be carried away from the well. The pavement may consist of cement Pl¹, or of slabs of stone, St. (See drawing.) (2.) The water-tight inner wall, pl, of the well should project above the ground to a height of at least 15 cm. (3.) The well should be securely closed by means of a stone cover, Pl, laid in cement, on the crown of the well pl; a cast-iron lid might also be used. The cover should gently slope downwards, and ought to project over the edge, pl, of the well. The cover must be provided with a hole, L, for the purposes of ventilation. To prevent contamination entering through this opening, the (4.) body of the pump Brll must be tightly fitted over it, so that communication with the outer air can only take place through the ventilator V, which is covered with wire gauze. (5.) The excess water flowing from the spout BrA must be carried away from the pump through b, on to the slanting pavement Pl. (6.) The inner wall of the well must be water-tight to a depth of at least 6 metres; for the author has shown that below this depth no micro-organisms capable of development exist in soil. Preferably, however, the well is made water-tight right down to the water-bearing strata, so that water can enter the well only at the bottom. The whole of the wall may be built of cement or Beton; or quarry stones M¹ or well-burnt bricks M² laid in mortar may be used, the whole of the inside being smoothed over with cement. The space between the soil E¹ and E², and the well-shaft M¹ and M², is finally filled up with clay or loam, or even cement, thus making the well perfectly water-tight.

PATENTS.

Improvements in Apparatus for Treating Sewage and other Impure Liquids by Electrolysis. W. Webster, junior, Blackheath. Eng. Pat. 472, January 11, 1888. 8d.

IMPROVEMENTS ON Eng. Pat. 1333 of 1887 (this Journal, 1888 441), which consist (1) in arranging a number of separate tanks with their electrodes connected in series with the main conductor; and (2) in arranging the electrodes in groups, the electrodes of each group being arranged in parallel circuit, while the several groups are connected in series, the objects being to diminish resistance and economise the electricity.—O. H.

Improvements in the Means or Appliances for Treating Sewage by Electrolytic Action and for Disposing of the Deposits thereof. W. Webster, junior, Blackheath. Eng. Pat. 1105, January 24, 1888. 8d.

FOR the iron plates described in Eng. Pat. 1333 (this Journal, 1888, 441) the inventor now substitutes aluminium wholly or in part, or "cast-iron plates in which pieces of graphite or other carbon are embedded by throwing them in just before cooling." The effluent is sometimes sent through a filtering chamber containing carbon electrodes. The walls and partitions of the tanks and sewers are made of ironstone, or of red or brown hematite. The sludge is mixed with lime refuse, for making land. (See also this Journal, 1888, 764; and 1889, 58.)—O. H.

Improved Construction and Arrangement of Apparatus for the Separation of Liquids and Semi-Liquids from Solids, especially applicable to Sewage, Sludge, Slip, Slurry, and other like Bodies. R. Muirhead, Maidstone. Eng. Pat. 1884, February 8, 1888. 11d.

THE improved apparatus used for the separation of liquid from solid matters consists of a rectangular box with two or more sides removable. One of these sides is used as

This question is exceedingly difficult to answer. The principal expeditions bacteriological methods in use have many faults. The micro-organisms which are at the bottom of many diseases are yet unknown, and many other organisms, though known, are not developed, and are therefore not discovered under the conditions employed in these bacteriological methods. The author is therefore of opinion that "prevention is better than cure;" and he strongly insists that the question of water supply shall be considered

a tube plate, and carries a number of tubes of cylindrical or other shape in cross-section, the sides perforated or otherwise constructed with filtering passages or slits, and sometimes covered with a stocking or bag of textile material, or the interior packed with porous or fibrous filtering substance. The sides of the box are forcibly held in position by a variety of devices illustrated, and in some cases the whole box may be swung on trunnions. The substance treated is forced into the interior of the box; the solid matter becomes compacted into a mass forming on the exterior of the tubes, and the liquid filtering into the interior of the tubes is conveyed to the outside of the machine by a suitably formed channel. Appropriate devices for the removal of the solid block, formed as described, from the interior of the tank, are shown.

PATENTS.

Improvements in Machines for the Production of Wood Fibre. P. A. Newton, London. From R. Steinmig, Grossbolkau, Germany. Eng. Pat. 2046, February 10, 1888. *11d.*

INSTEAD of using grindstones for the production of mechanical wood pulp, as hitherto, the inventor uses a specially prepared grinding machine, consisting of a wooden or metal disc, the peripheries or sides of which are covered with a number of cutting edges made from steel or other hard metal, securely fastened by means of wooden wedges (Fig. 1).

Fig. 1.

The cutting edges may be of different forms, as shown by the sections (Fig. 2), and they should project from the

Fig. 2.

surface of the disc to about one inch, and at such a distance from each other that they do not touch when bent by the pressure of the wood against them.

Such an arrangement is said to give a long soft flexible fibre at small cost for labour.—E. J. B.

Improvements in or relating to Aseptic or Antiseptic Paper and the like, applicable for Use as Bandages for Wounds, or for Hygienic or Preservative Purposes. W. P. Thompson, Liverpool. From P. Matcovitch and A. Grossich, Fiume, Hungary. Eng. Pat. 7854, May 29, 1888. *6d.*

THIS specification relates to the manufacture of aseptic paper from 75 per cent. of linen and 25 per cent. of cotton, the pulp being washed in an alkaline solution, and subsequently treated with chlorine water, alcohol, "phenic acid," &c. The antiseptics used are iodoform, corrosive sublimate, thymol, carbolic acid, salol, picric acid, salicylic acid, and the like.—E. G. C.

Apparatus for removing Metallic Particles from Paper Pulp. H. H. Lake, London. From C. H. Atkins, Boston, U.S.A. Eng. Pat. 17,227, November 27, 1888. *8d.*

THE pulp is made to flow, on its way to the pulp vat E, along a copper trough A, the recesses, B, of which are filled with mercury. Below the trough are placed a number of electro-magnets, D. The latter remove from the

pulp any magnetic particles, such as fragments of steel or iron, while the mercury retains any particle of brass, copper, or bronze.—E. J. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Ammonium Bromide. K. Thümmel. Arch. Pharm. 1888, 26, 1124.

ACCORDING to the German Pharmacopœia (H.), ammonium bromide should not redden litmus paper. The author finds, however, that ammonium bromide, prepared in a variety of ways, invariably reddens litmus paper, either when simply placed upon the paper, or when tested in a 1:5 solution. He further finds that by the action of bromine upon ammonia, nitrogen is evolved and ammonium bromide alone formed, as long as ammonia is in excess, a statement which is contradictory to the observation of E. Schmidt (Pharm. Chem. 1, 484) that by this means a small quantity of an oxygenated product results.—C. A. K.

Basic Bismuth Nitrate (Bismuthum subnitricum, B.P.). F. Belliogròdt. Apoth. Zeit. 1889, 4, 29.

THIS product, as obtained from the best German manufacturers, has been found to contain so much lead, that the presence of the latter is rendered evident by the taste.

—C. A. K.

Iodoform. B. Fischer. Pharm. Zeit. 1889, 34, 31.

THE author has examined into the cause of the pink colouration acquired by iodoform when dissolved in ether, &c., and finds that the ethereal solution of perfectly pure iodoform acquires a dark tint under ordinary conditions. But if the iodoform and the solvent be freed from air, the solution is of a pale yellow colour as long as air is completely excluded; this solution darkens immediately it is exposed to air, owing to the separation of free iodine. Certain impurities, either in the iodoform or in the solvent, appear to hinder this decomposition; in samples of iodoform containing amylalcohol, pyridine bases, and acetamide respectively, the darkening of the ethereal solution was not observed, so that in all probability these substances either take up the oxygen (from the air) in the solvent, or else the separated iodine.—C. A. K.

The Alkaloids of the Areca Nut. E. Jahus. Ber. 21, 3404—3409.

THE areca or betel nut is the fruit of the areca palm (*Areca catechu*), and is an important article of commerce. It contains tannin, fat, and alkaloid substances. The latter are extracted as follows:—The powdered seeds are extracted three times in the cold with water to which 2 grms. of concentrated sulphuric acid are added for every 1 kilo. of seed.

The filtrate is evaporated, and after filtration, potassium bismuth iodide, and sulphuric acid added. The red crystalline precipitate is decomposed with barium carbonate and water. The alkaloids dissolve, whilst bismuth oxyiodide, colouring matter, &c., remain undissolved. The filtrate is evaporated, baryta solution added, and extracted with ether. The latter extracts an oily substance called *arecoline*. The residue is neutralised with sulphuric acid, and the remaining alkaloids extracted by treating successively with silver sulphate, baryta, and carbonic acid, and extracting the dry residue with absolute alcohol or chloroform. A second alkaloid goes into solution, and a third, *arecaine*, remains undissolved. The yield of *arecoline* is '07 to 1 per cent., of *arecaine*, '1 per cent.

Arecoline is a colourless oily liquid with a strongly alkaline reaction soluble in the usual solvents. It is volatile, and distils at about 220°. The hydrobromide has the formula $C_8H_{13}NO_2 \cdot HBr$. The hydrochloride forms double salts with auric and platonic chlorides.

It acts as a strong poison. *Arecaine* forms colourless crystals soluble in dilute alcohol and water. It contains one molecule of water of crystallisation which it loses at 100°. Its formula is $C_7H_{11}NO_2 + H_2O$. Like *arecoline* it forms double salts with platonic and auric chlorides.

—J. B. C.

Preparation of Concentrated Formic Acid. M. Maquenne. Bull. Soc. Chim. 1888, 662—664.

THE author finds that, although formic acid is decomposed by sulphuric acid into carbon monoxide, the reaction only occurs when both acids are concentrated, and that dilute formic acid may be distilled, under diminished pressure, over concentrated sulphuric acid without decomposition. For instance, commercial formic acid containing 45—50 per cent. of water, on distilling on the water-bath with an equal weight of strong sulphuric at 66° B., yields formic acid of 84—85 per cent., and a second distillation yields an acid of 98 per cent. strength. The lower the temperature at which the acid is distilled the better, and the less the acid carried away by the exhauster. A certain quantity of more dilute formic acid remains behind in the retort, and may be further concentrated.—J. B. C.

The Manufacture of Iodoform. H. Suilliot and H. Raynaud. Bull. Soc. Chim. 51, 3—4.

THE authors base their process on the reaction between acetone and iodine, and by the use of hydrochlorite at a later stage, practically recover the whole of the iodine in the final product. One molecule of acetone and six of iodine in presence of sodium hydrate yield one molecule of iodoform, one-half of the iodine forming sodium iodide. If sodium hypochlorite be then added, a further molecule of acetone is attacked, yielding iodoform. There is no formation of chloroform or iodate. The mode of procedure is to dissolve 50 parts of potassium iodide, six parts of acetone, and two parts of sodium hydrate, in one or two litres of cold water. On adding to this a dilute solution of sodium hypochlorite, drop by drop, with agitation, a precipitation of iodoform ensues, which agglomerates rapidly. The hypochlorite is added until all acetone or iodine has disappeared. The results are close on the calculated quantities. As the presence of neutral salts of the alkalis do not interfere with the reaction, crude caustic liquors may be used, if previously freed from sulphides, sulphites, &c. The liquor decanted from the precipitate contains only traces of iodine.

—G. H. B.

On the Employment of Low Temperature in the Preparation of Pharmaceutical Extracts. L. A. Adrian. Bull. Soc. Chim. 1889, 234—240.

THE advantage of employing methods of freezing for the concentration of solutions of organic substances has long been recognised by many investigators whose views are cited in this article, and the author is engaged in working out a method for operating on an industrial scale in the

production of extracts sufficiently concentrated to be suitable for further evaporation in the vacuum apparatus described and illustrated on pages 184–185. The extracts as obtained by the usual methods (maceration, infusion, &c.) in dilute aqueous solution are submitted to a low temperature until the greater part of the water separates in the form of ice, leaving the dissolved substances in that portion which remains liquid; but the separation is always more or less imperfect, as the ice in the process of formation occludes much of the mother-liquor. The author has aimed at improving the means of separating the ice from the liquid portion, and uses a machine on the ammonia system for operating on 200 kilos. of liquid at one time. The filtered solution is placed in moulds and submitted to cold until the frozen blocks have a temperature of -10°C ., and are then very hard. The blocks are then removed and placed in a crushing machine of special construction which, in less than a minute, reduces them to the condition of snow. This snow is transferred to an apparatus which, in about 20 minutes, separates 75 per cent. of the water in the solid state and almost free from dissolved matters, whilst the liquid portion is again treated as before but at a still lower temperature. (No description is given of the apparatus employed.) Two congelations yield 12 to 15 per cent. of the original solution in the form of a syrupy extract, which is concentrated to the desired degree in the vacuum apparatus. The avoidance of high temperatures and of loss of time in all the operations tends to preserve the original potency of the organic principles in the extract, and the author believes that, should the process become generally employed, it will become necessary to verify experimentally the activity of many extracts so obtained; for example, of belladonna, hyoscyamus, hemlock, &c.

—G. H. B.

On the Active Principle of *Strophantus glabre*.

M. Arnaud. *Compt. Rend.* **107**, 1162–1164.

The author described recently two crystallised substances, ouabaine, $\text{C}_{20}\text{H}_{36}\text{O}_{12}$, obtained from the wood of *Acokanthera Ouabaïto*, and strophantine, $\text{C}_{31}\text{H}_{44}\text{O}_{12}$, from the seeds of *Strophantus Kombé*. (This Journal, 1888, 586.) He has since examined the crystallised substance contained in the seeds of *Strophantus glabre* of Gabon, which furnish the arrow poison of the Pahouin tribe. This principle appears to be identical with ouabaine, which exhibits toxic effects almost identical with strophantine. Hardy and Gallois have also described a crystallised substance from *Strophantus glabre*, but imperfectly for want of material. These substances are glucosides, and low temperatures must be adhered to in the extraction in order to avoid decomposition. The crystals of glucoside from the seeds of *Strophantus glabre* (which gave the remarkably high yield of $\frac{1}{2}$ –7 per cent.) are transparent, very slender, and of rectangular form; by slow crystallisation they are thicker and become opaque. The melting point is about 185°C ., but a pasty condition obscures the exact point of fusion. The crystals dissolve in 150 parts of water at 8°C .. The aqueous solution exhibits left-handed polarisation, and a solution containing 6.5 per cent. at 50°C ., gave the coefficient $\alpha_D = -33.8$. Under the influence of dilute acids and heat the substance splits up into a reducing sugar and a peculiar insoluble resin. The crystals of ouabaine have the formula $\text{C}_{20}\text{H}_{36}\text{O}_{12} \cdot 7\text{H}_2\text{O}$, of which only six molecules of water are given off at 100°C .—G. H. B.

Ouabaine. M. Arnaud. *Bull. Soc. Chim.* **51**, 10–11.

THIS paper is substantially a shortened report of the above, with the additional information that ouabaine is an ether of isodulcite, whilst strophantine yields glucose on splitting up the glucoside.—G. H. B.

Notes on Mercury-Ammonium Compounds. C. Rammelsberg. *J. Prakt. Chem.* **38**, 1888, 558–569.

1. *Mercuric Oxide and Ammonia*.—Yellow amorphous mercuric oxide was employed for the experiments. If gaseous ammonia be allowed to act upon it at common

temperatures, a pale yellow product is obtained, the analysis of which corresponds with the formula $2\text{HgO} + \text{NH}_3$. This compound is very stable, and does not lose any ammonia in the air or on boiling with water. Even strong bases, like sodium hydrate, liberate, on continued boiling, only 0.23 per cent. of ammonia. Kept over time, concentrated sulphuric acid or phosphorus pentoxide, the loss in weight becomes constant after some time, and the substance assumes a light-brown colour. The weight lost indicates that $2\text{HgO} + \text{NH}_3$ liberates one molecule of water on drying, and is thereby converted into Hg_2ONH . It is very probable that $2\text{HgO} + \text{NH}_3$ is the hydrate of mercuric-ammonium hydroxide, thus: $\text{NH}_2\text{Hg}_2\text{OH} + \text{H}_2\text{O}$. It presents all the properties of a base, as will be seen further on. If mercuric oxide be treated with ammonia-liquor in the heat or in the cold, a pale yellow product is obtained, which is usually called "Millon's base." According to Millon it has the formula $2\text{HgO} + \text{NH}_3 + \text{H}_2\text{O}$, whereas the analysis of the author points to the formula $3(2\text{HgO} + \text{NH}_3) + 2\text{H}_2\text{O}$. Dried over sulphuric acid, it loses its water and becomes identical with the base obtained by the dry method. But whereas the latter loses its water, if dried at common temperatures, Millon's base loses under similar conditions, at first only $\frac{2}{3}$ ths of its water, and the rest on warming only. Millon's base, therefore, retains a portion of its water more firmly than the base produced by the dry method. However, both bases yield with acids identical salts. The two compounds may have a different constitution; thus—

Base by dry method.

Millon's base.

2. *Mercury-Ammonium Chloride*.—Dilute hydrochloric acid changes the two bases into an insoluble yellow chloride. It is also obtained by boiling the so called "white precipitate" with water or sodium hydrate. It has the formula $\text{NH}_2\text{Hg}_2\text{Cl} + \text{H}_2\text{O}$. Its water is only completely given off at 200°C . 3. *Double Salts of Mercury-Ammonium Chloride and Ammonium Chloride (White Precipitate)*.—Mercury-ammonium chloride combines with ammonium chloride in two proportions. Both compounds are called white precipitate. They are decomposed by warm water, ammonium chloride going into solution and mercuric-ammonium chloride being left behind. The compound of the latter with one molecule of ammonium chloride does not fuse on heating, and is called "infusible precipitate," whereas the compound containing three molecules of ammonium chloride fuses on heating, and is termed "fusible precipitate." The latter can be made from the former by boiling with ammonium chloride solution. Amorphous mercuric oxide and Millon's base are converted into fusible precipitate by boiling with ammonium chloride. 4. *Mercury-Ammonium Sulphate*.—Millon's base changes on boiling with dilute sulphuric acid into an insoluble pale yellow sulphate, which turns grey in the light. Its formula is $(\text{NH}_2\text{Hg}_2)_2\text{SO}_4 + 2\text{H}_2\text{O}$. 5. *Mercury-Ammonium Nitrate*.—If the mercury-ammonium base be heated with dilute nitric acid, it forms a yellow insoluble nitrate of the formula $\text{NH}_2\text{Hg}_2\text{NO}_3$. It appears to be identical with the product obtained by treating mercuric oxide with a solution of ammonium nitrate. 6. *Mercury-Ammonium Carbonate*.—The base boiled with a solution of sodium carbonate forms a white carbonate (normal), $(\text{NH}_2\text{Hg}_2)_2\text{CO}_3 + 2\text{H}_2\text{O}$. It is also obtained from mercuric oxide and ammonium carbonate. 7. *Mercury-Ammonium Phosphate*.—Boiled with an excess of phosphoric acid, the base is converted into a yellow phosphate, which becomes grey in the light. It is a basic salt and has the formula—

8. *Mercury-Ammonium Bromate*.—If ammonia be added to a solution of mercuric bromate, a yellow precipitate is obtained which has the formula $2(\text{NH}_2\text{Hg}_2\text{BrO}_3) + 3\text{H}_2\text{O}$. On heating it is decomposed with a loud detonation. 9. *Mercury-Ammonium Iodate*.—Amorphous mercuric oxide, digested with aqueous iodic acid, is rapidly converted into a white iodate, HgI_2O_6 . If the latter be heated with ammonia-

liquor it turns yellow. The analysis of this yellow product presents great difficulties and the figures obtained point to the formula—

10. *Mercury-Ammonium Periodate*.—Mercuric oxide treated with periodic acid in excess, is changed into pentamercurey periodate $\text{Hg}_5\text{I}_2\text{O}_{12}$. The latter, digested with ammonia, yields a light yellow substance, the analysis of which is very difficult. The figures obtained point to the formula—

—S. H.

On the Action of Cuprous Chloride on Iron Potassium Sulphide and the Preparation of Artificial Copper Pyrites. R. Schneider. J. Prakt. Chem. 33, 1888, 569–582.

AN ammoniacal solution of cuprous chloride is allowed to act in the cold on crystals of iron-potassium sulphide, both substances being taken in equivalent proportions. The reaction proceeds at once, but drags towards the end and requires nearly 30 hours before it is finished. The crystals obtained correspond with the empirical formula Cu_2FeS_3 . They present the same chemical properties as natural copper pyrites, with which they are, in fact, identical. The reaction is represented by the equation—

The author is of opinion that the formula of natural copper pyrites should be written $\text{Cu}_2\text{S} \cdot \text{FeS}_3$ instead of $\text{CuS} \cdot \text{FeS}$.

—S. H.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Salts of Gold used in Photography. A. Lainer. Dingl. Polyt. J. 271, 30–35.

THE salts of gold generally in use among photographers are auric chloride, potassium auric chloride, and sodium auric chloride. If it be desired to substitute one for the other in the toning solution, it is customary to assume that the quantity of gold they contain will correspond to their equivalent weights. That such an assumption may be fallacious is shown by the fact that many preparations have a considerable residue when treated with ether-alcohol, consisting of alkaline chlorides. The subject presents three aspects: (1) analytical, as to the purity of the salts; (2) pecuniary, as to their money value; (3) photographic, as to their toning power.

With regard to (1): Auric chloride often contains free gold, actually, or potentially as aurous chloride; this is due to overheating in its preparation. On the other hand, by insufficient evaporation, hydrochloric acid may be left in, as hydrogen auric chloride, $\text{AuCl}_3\text{HCl} \cdot 3 \text{H}_2\text{O}$.

Two samples of commercial "gold chloride" were found to contain 42.11 and 51.75 per cent., respectively, of Au, instead of 57.96 per cent., which is the proportion present in $\text{AuCl}_3 \cdot 2 \text{H}_2\text{O}$. The former contained a notable quantity of potassium chloride, while the latter was contaminated with no foreign metal except copper, of which the chloride was present to the extent of 0.5 per cent. A sample of potassium auric chloride was adulterated with 10.4 per cent. of added potassium chloride, which was easily detected on shaking with ether. Two samples of sodium auric chloride contained 17.73 and 20.55 per cent. of Au respectively, in place of 49.43 per cent., which is the quantity present in $\text{AuCl}_3\text{NaCl} \cdot 2 \text{H}_2\text{O}$; these numbers correspond to the presence of 64 and 58 per cent. of added sodium chloride respectively. In the latter specimen a trace of copper was found.

(2.) In respect of the money value of the commercial gold salts, it was found that the price was fairly close to the actual quantity of gold they contained, as the following table shows:—

Sample.	Weight of Gold.	Value.	Price.
Grm.	Grm.	Fl. kr.	Fl. kr.
Auric chloride	1	0.4211	1 15
" "	1	0.5175	1 46
Sodium auric chloride ..	1	0.1773	0 48
" " " ..	1	0.2055	0 55

The weight of salt in the nominally 2-grm. bottles was generally nearly correct, though usually inclined to be a little low.

(3.) From the above facts it appears that the photographer cannot make up his toning solution of the right strength by taking equivalent weights of the commercial gold salts. This is in itself objectionable, but what is worse is the presence of such excessive quantities of sodium chloride as were found in the samples examined, as they have a tendency to produce a reddish tone on the prints. Hydrochloric acid is also most deleterious, delaying the toning and causing the formation of blisters; even after neutralisation it is injurious on account of its forming so much more alkaline chloride. The presence of cupric chloride mentioned above is found to be distinctly advantageous to the toning properties of the bath. The large variations in the proportion of gold in different preparations sold under the same name go far to explain how the almost innumerable receipts for toning solutions now extant, have arisen.

Photographers who are in the habit of preparing their own gold salts are of course free from these inconveniences, but for those who buy them, the best plan is to purchase only definitely crystallised samples.—B. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

Bellite Experiments. Engineer, 1889, 116.

ON Tuesday last, February 5th, a programme of experiments with this explosive was carried out at Wangey Hall Farm, Chadwell Heath, in the presence of Sir I. Lowthian Bell, and other scientific visitors, including many of the attachés of foreign Powers. Bellite in its character and composition closely resembles roborite, but it is claimed for it that it possesses special advantages in the total absence of sulphur and chlorine, and consequently the property of being flameless, and thus specially for being adapted for work in "fiery" mines. Bellite consists of a mixture of five parts by weight of nitrate of ammonium and one of dinitrobenzene. The trials were conducted under the direction of Mr. C. Napier Blake, the arrangements being made by Mr. Preece Williams.

The inventor, Mr. Carl Lamm, claims for bellite the following advantages:—(1) That bellite is one of the most powerful explosives known; (2) that it is more powerful than either gun-cotton, dynamite, or gunpowder; (3) that it possesses qualities of safety entirely foreign to explosive substances generally; (4) that bellite presents no danger whatever in manufacture; (5) that it cannot be made to explode by friction; (6) that it cannot be made to explode by shock or by pressure; (7) that it cannot be made to explode by electricity or by lightning; (8) that bellite cannot be made to explode by fire; (9) that it cannot be made to explode by any means except by the aid of a detonating cap, and is therefore absolutely safe; (10) that on bellite being exploded no noxious gases are given off, as is the case with dynamite and all nitroglycerin compounds; (11) that bellite made expressly for coal or rock blasting does not shatter like dynamite, but forces the coal or rock out in larger blocks, making but a very small percentage of dust; (12) that it does not undergo any chemical

change from time nor from atmospheric influences, always retaining its non-explosive character until the fulminating cap is applied to it; (13) that it can be used in shells that would prove of a terribly destructive character. Dynamite cannot be so applied, as the concussion produced by ignition of the gun charge would be liable to explode the shell and burst the gun. Bellite shells, however, may be fired without any such risk, thus solving the problem of firing high explosives from ordinary guns, hitherto an impossibility. (14) That bellite can be manufactured in tropical climates, which is not possible with dynamite; (15) that it can be transported by land or sea with perfect safety, being carried in Sweden as ordinary merchandise; (16) that it requires no thawing in the coldest weather, like dynamite, consequently much time is saved; (17) that it can be profitably sold at a lower price than dynamite or any other nitroglycerin compound. At present there are about 60 factories in Europe making dynamite and similar compositions, producing annually 40,000,000 lbs.

The programme was commenced by firing a charge of 1½ lb. of bellite in a can under water. As the bellite was enclosed in a water-tight case there was nothing in this test to notice.

(2.) A bellite 4-oz. charge—which somewhat resembles a stick of sulphur with a perforation at one end—was broken in two, the solid end being thrown into a coal fire, where it melted and burnt without attracting notice, and the perforated end being exploded by means of a fuse and detonator, on a ½-in. boiler plate, which it bulged. This illustrated the fact that bellite will not explode by ordinary combustion, while its action on ignition by a detonator is very powerful.

(3.) An iron 120-lb. weight was dropped from a height of about 16 ft. on five charges of bellite laid on an iron plate. The first blow not being quite end on, this was repeated, when the bellite was crushed to powder without explosion.

(4.) The crushed bellite thus produced was then placed in a tin which held 5 oz., and fired by a detonator in contact with an old S.E.R. iron steel-faced rail, which was fractured. This illustrated the power of bellite to resist explosion under a blow when in contact with iron.

(5.) In a hole 3 ft. deep was buried 1 lb. of blasting powder mixed up with naked bellite cartridges or charges, and the powder fired by a plain powder fuse, when the bellite was thrown about and blackened, and the surface burnt in places, but apparently none of it was exploded.

(6.) A charge of bellite was fired like a bullet from a small-arm, "No. 8"—½-in.—bore, against a ½-in. boiler plate. Bellite was found in small pieces adhering to the face of the plate unexploded.

(7.) The propelling power of bellite was next shown by the following experiment:—A 32-lb. shot was discharged from a short mortar, first by a charge of ½ lb. of powder—Curtis and Harvey's—and then by ½ lb. of bellite. In the former case the shot fell at 40½ yards from the mortar, and in the second at about 95 yards, illustrating the great superiority of bellite over the double weight of powder fired under these conditions, for propulsion.

(8.) Charges of dynamite and bellite 4 oz. each were placed on similar ½-in. boiler plates, and after being covered with clay, which was pressed over them, was fired. The effects were very nearly identical in this case. It is, however, said that experience has shown that the injury effected by dynamite is generally more local, and that of bellite more distributed.

(9.) The fuses of mines in the earth charged with gunpowder and bellite were now ignited. The powder exploded, but the bellite fuses failed.

(10.) A charge of 8 lb. (10s. worth) of bellite, which had been buried 3 ft. beneath a length of 60 ft. of railway line, laid on chairs fixed on cross sleepers, with fishes, &c., complete, was now exploded by the usual detonating fuse. The entire structure for many feet was lifted high in the air, the rails being both broken through in one place, while one rail was bent at some feet distance from the point of fracture, the fishes of the other rail being broken through at a nearly equal distance. The sleepers were torn and split, and one chair broken. A crater was opened in the ground about 12 ft. in diameter.

Some of its properties were necessarily not tested; for example, its freedom from all flame, and the harmless character claimed for its products of combustion. Then, again, its power to explode when in contact with water was not exhibited. It may be noticed in addition to what has been mentioned above with regard to the 13th claim put forward by the inventor, namely, its suitability for bursting charges of gun shells, that a delay action arrangement has been devised to enable steel shells to perforate armour before explosion takes place.—W. S.

Blasting Gelatin and Bellite. J. Guthrie Kerr. Glasgow Herald, March 6, 1889.

IN a lecture by the above-named, before the Philosophical Society of Kilmarnock, the following comparison was made between the powerful explosives "bellite" and "blasting gelatin." Nitroglycerin exudes from dynamite immersed in water, and Nobel's next effort was so to fix the nitroglycerin that the danger arising from this—the cause of several accidents—might be averted. Further, it seemed desirable that the fixing compound should not be inert like "Kieselguhr." This was effected by utilising Pelouze's discovery of gun-cotton (trinitrocellulose) in 1838. This substance, itself an explosive, but with slight defect of oxygen, was found to dissolve in nitroglycerin, which contains for explosion slight excess of oxygen, and with these two was formed the theoretically perfect explosive—"blasting gelatin." The parts are 3 per cent. of gun-cotton to 97 per cent. of nitroglycerin. In explosive effect blasting gelatin is 50 per cent. better than dynamite, and is described by Sir Frederick Abel, our greatest authority on explosives, as the cheapest, the safest, and most perfect. It is entirely unaffected by water, and cartridges which have been immersed for seven years in water have at the end of that time developed their full power when detonated. Gelatin-dynamite is a modification of blasting gelatin, somewhat cheaper in manufacture, and having in use more of a heaving action. It is made of 80 per cent. of blasting gelatin, not quite gelatinous, wood meal and saltpetre forming the other 20 per cent., and is largely used in the fiery mines in England, as the cartridge is Settle's patent. This invention consists of a water-tight bag, in which the cartridge is kept in position in the middle of the water in the bag by tin supports. The charge is exploded by a detonator set off by a current of electricity. No flame follows the explosion, and accordingly the risk from fire-damp is minimised. Within the last two years attempts have been made to meet the disadvantages of forming such large bore-holes as this invention requires, and to diminish the trouble which the miner has in manipulating the apparatus. The explosives for which is claimed at least equal power but entire absence of flame are known as roborite, carbonite, and bellite. These compounds are nitro-substitution derivatives of benzene associated with nitrate of ammonium. In bellite, the discovery of Carl Launm in 1887, the proportions are five parts of the ammonium salt to one part of dinitrobenzene. This explosive is said to be 30 per cent. stronger than dynamite, absolutely safe for transport, and flameless. The experiments lately made in the Cleveland district pronouncedly show that bellite may be safely subjected to the roughest treatment. Regarding entire absence of flame in the explosion of those nitrobenzene compounds, there seemed to be want of evidence as to the effects of other than comparatively small charges under favourable conditions. In the meantime the claim could not be considered as made good, whatever the promise might be. Compared with blasting gelatin, bellite is inferior so far as concerns power of withstanding water, as might be inferred from the presence of such a large proportion of nitrate of ammonia. If, as a protection against water it be covered with a waterproof mixture, it becomes less adaptable for the completely filling up of bore-holes in blasting operations.—W. S.

PATENTS.

An Improved Apparatus for utilising an Explosive Compound for Blasting or other Purposes. R. Pamshon and R. R. Vizer, London. Eng. Pat. 2428, May 12, 1883. Amended November 13, 1888. 6d.

This invention relates to a cartridge in which nitric and picric acids can be separately contained, the object being to enable these two acids to be utilised for blasting purposes, &c.

The former two claims are withdrawn, and another substituted, which is explained by the foregoing.—C. N. H.

Improvements in the Manufacture of Explosives. A. V. Newton, London. From A. Nobel, Paris, France. Eng. Pat. 1,471, January 31, 1888. 6d.

"The object of this invention is to combine the substances, nitroglycerine and nitrated cellulose, with or without nitrated starch or nitro-dextrine, or both, so as to produce an explosive substance of a horny or semi-horny character, and capable of being reduced to grains suitable for use as a propeller of projectiles."

In carrying out the invention, varying proportions of the ingredients are taken according to the result desired. Camphor or other solvents, such as benzol, acetone, &c., are added with a view to facilitate the solvent action of the nitroglycerin on the nitrocellulose.

The limit of variation as regards the relative proportions of nitroglycerin and nitrocellulose, which permits of obtaining a compound consistent enough to be granulated, is very wide. But when the proportion of nitroglycerin exceeds two-thirds of the compound it is rather too soft, and when, on the contrary, nitrocellulose is in excess of two-thirds it becomes too tough and hard to be easily granulated.

For firearms "an excellent explosive is obtained by dissolving 20 to 30 parts of nitrated, soluble, pulped cotton in 100 parts of nitroglycerin and 20 parts of camphor, adding then 100 parts of nitrostarch, containing about 12 to 12½ per cent. of nitrogen, and 200 parts of nitro-dextrine of the same tenour of nitrogen. The material is easily formed by simply kneading it together at a temperature of, say, 60° C., or better still by malaxation between rollers, regulating the temperature so as not to have it too sticky. It is, after having become homogeneous, rolled out into thin sheets and cut up into grains, or moulded, if desired."

Oxygen yielding salts, such as nitrates and chlorates, or powdered explosives, such as picrates, are easily incorporated in the above mixture at a temperature of 60° C. The quantity of such salts to be added is limited to the capability of easy practical incorporation, and varies according to the necessity for more or less complete combustion on explosion.—C. N. H.

XXIII.—ANALYTICAL CHEMISTRY.

A New Method of Estimating Temperatures.
Engineering, 1889, 115.

An instrument has been recently made by Messrs. Dueretot, of Paris, to the designs of Messrs. Nouël and Mesuré, to utilise the colour of heated iron so as to determine its temperature. Could these colours, as they pass from red through orange to dazzling white, be reproduced with certainty on the retina, they would show that the corresponding temperature had been attained. Owing to physical defects, however, the eye is unable to properly distinguish these different shades. This pyrometer glass, in brief, consists of a telescope fitted with a couple of Nicol's prisms, one of which acts as analyser to the other; a plate of quartz also being placed between the two. The light from a heated object on passing through the first Nicol is polarised, and the plane of this polarisation is, as the light traverses the quartz plate, turned round through an angle proportional to the thickness of the quartz, and nearly inversely to the wave length of

the light—that is to say, its colour. Hence, assuming the Nicols were set so that if the quartz were removed, the polarised ray was quenched by the second, then on replacing the quartz the second Nicol would have to be rotated through a certain angle to again quench the light, this angle, of course, being equal to the rotation of the plane of polarisation by the quartz, and therefore dependent on the colour of the rays passing through. The second Nicol is carried by a tube fitted with a graduated head, so that this angle can readily be observed, and to every graduation corresponds one colour, and one only. In practice, complete extinction never occurs, but at a certain point the colour of the transmitted light changes from green to red, and this point is taken as the angle to be measured.—W. S.

J. Wiborgh's Air Pyrometer. Dingl. Polyt. J. 271, 118—124.

Of all the materials by the expansion of which high temperatures are measured, air is probably the most suitable, as its coefficient of expansion is, as far as we know, very constant. Pyrometers in which it is used have often been devised, and fall naturally into two classes:—

- (1.) That in which the volume of the air is kept constant, and the increase of pressure measured.
- (2.) That in which the pressure of the air is kept constant, and its increase in volume measured.

The chief objection to the first is that, at comparatively low temperatures, the pressure has risen already to an inconvenient extent, a pressure of an additional atmosphere

Fig. 1.

corresponding only to a temperature of 272° C.; while in the case of the second, there is the great disadvantage that, as the temperature rises, an increment of a given number of degrees corresponds to a continually diminishing increase in the volume of the air. Consequently, in order to get an accurate reading, it is not only imperative that the limb of the manometer be finely graduated, but also that precaution be taken to level the mercury very exactly.

To achieve this result, Petterson has devised an appendage marked E in Fig. 1, consisting of a small manometer containing water instead of mercury. When the level of the mercury in the large manometer B V has been adjusted as closely as possible, communication between it and E is made by means of the three-way cock D, and the adjustment continued until E shows it to be exact. Even with this addition, accuracy in the indications of the instrument can only be attained by surrounding that part of the manometer which measures the increase in volume by a water jacket, so as to keep it at a known temperature, thereby making it somewhat clumsy.

Wiborgh's pyrometer depends on a new principle, and is free from these defects.

Fig. 2.

In Figure 1, which represents the apparatus diagrammatically, V is the bulb, containing air, which is exposed to the temperature to be measured, A a capillary tube so small that its volume may be neglected, V₁ the near limb of the manometer, which has its volume between the marks *m* and *m*¹, known, B the other limb, and K a rubber reservoir of mercury. The action is as follows: V being raised to the temperature to be measured while the cock D is open to the air, and the level of the mercury is brought to *m*¹, the temperature of the air in the limb V₁ of the manometer is taken, the cock closed, and mercury forced into the manometer by the rubber ball K until it stands at *m* permanently, showing that the air added to the contents of V has attained its temperature.

The increased pressure requisite to effect this is read off, and the temperature can then be calculated from the following considerations: If T be the temperature to be measured, and *t* that of the portion of air forced into the bulb, V the volume of the bulb, and V₁ that of the air forced in, then as V is raised through T-*t* degrees, its volume under atmospheric pressure would be V [1 + α (T-*t*)] where α is the coefficient of expansion of air. Therefore the total air in the bulb would measure, under atmospheric pressure, V + V₁ [1 + α (T-*t*)]. But as it is constrained to occupy a volume V₁, being under the additional pressure of the mercury in the manometer, which we will call *h*, we have, taking H as the height of the barometer at the time, the equation:—

$$\frac{V + V_1 [1 + \alpha (T - t)]}{H + h} H = V$$

Sprung points out (*Oesterr. Zeits. f. Berg. u. Huttenwesen*, 1889, 2) that this is erroneous, inasmuch as α is the increase in volume of a unit volume of air when raised from 0° C. to 1° C., and therefore the volume occupied by V₁, after being raised from *t* to T, is not V₁ + V₁ α (T-*t*), but V₁ + V₁ α (T-*t*). Where V₁ is the volume, V₁ would occupy when cooled from T to 0° C. It is far simpler to dispense with the use of the symbol α, and make the temperature absolute, in which case we have—

$$\frac{V + V_1 \left(\frac{T + 273}{t + 273} \right)}{H + h} H = V$$

(A correction for the expansibility of the material of which the bulb is composed can be inserted if thought necessary.)

This equation can be written—

$$h = H \frac{V_1}{V} \left(\frac{T + 273}{t + 273} \right)$$

which shows that a given increment of temperature at any part of the range of the pyrometer produces a constant increment in the reading (*h*) of the instrument. Further, the apparatus can be constructed of any required degree of delicacy by varying the relation between V and V₁. Its zero point is determined by making a determination in the manner described above, when T = *t*. It can be used for measuring temperatures lower than *t*, in which case *h* becomes negative.

The actual construction is shown in Fig. 2. The thermometer bulb V is of porcelain, and is in one piece with the capillary tube of the same material marked A. This tube has an external diameter of 1.0 mm. and a bore of 0.5 mm. It is connected by the metal cap II and tube II₁ with the manometer B V₁ B₁ which has an enlargement at *m*, which serves to contain the volume of air that is forced into V₁ and which is conveniently $\frac{1}{10}$ th of its volume. An air-trap below V₁ is provided, as shown in the figure. The india-rubber reservoir K is enclosed in a metal box fitted with a lid which can be raised and depressed by means of the screw S, and thus mercury forced evenly into the manometer tube.—B. B.

Detection of Antimony in Minerals. A. Johnstone.

Chem. News, 58, 296—297, and 59, 15.

By adding a drop of ammonium sulphide to the white incrustation of Sb₂O₃, obtained by heating an antimoniferous mineral with fusion mixture on charcoal in the inner flame of the blowpipe, the very characteristic reddish or orange sulphide of antimony is produced. With larger quantities the reaction may be obtained in an open tube.

—O. H.

The Testing of Reagents. L. L. de Koninck. Zeits. f. angew. Chem. 1889, 4.

Lead Peroxide often contains manganese, likewise as peroxide. Boiling with dilute nitric acid is not sufficient to distinguish this. If, however, the peroxide be warmed with excess of concentrated sulphuric acid, and then, on cooling, treated with water and an additional quantity of peroxide, and again heated, presence of manganese is denoted by a red colouration of the solution, due to permanganic acid.

Ether.—Presence of free sulphur and consequent probable presence of organic sulphur may easily be recognised by shaking with a drop of pure mercury. In presence of only a very small quantity of sulphur, the surface of the mercury becomes dull; if a relatively large quantity of sulphur be present, the whole liquid becomes grey or black.

Chloroform.—Pure chloroform does not reduce an alkaline solution of potassium permanganate in the cold; if alcohol be present, reduction takes place. Caustic soda and caustic potash, however, generally contain organic compounds, consequently it is best to use a solution of permanganate in saturated baryta water.

Such a solution, when added to chloroform containing alcohol, turns green, owing to formation of manganate.

—T. L. B.

The Action of Sulphuretted Hydrogen on Solutions of Sulphate of Zinc. H. Baubigny. *Compt. Rend.* **107**, 1148—1150.

It has been stated by Berzelius that a current of sulphuretted hydrogen will precipitate a portion of the metal from a saturated solution of zinc sulphate, but the action stops when the solution has developed a certain degree of acidity. The author has examined this reaction in the case of dilute solutions, and finds that a more qualified statement is required for a generalisation of the facts. A solution of sulphate or chloride of zinc (always in the state of neutral salt) containing 0.3 gm. of salt in 100 cc. will be completely precipitated after saturation with sulphuretted hydrogen, and on being left in a closed vessel for several hours at the ordinary temperature. If the quantity of dissolved salt be doubled the precipitation is less perfect; after five hours the solution contained from 0.004 to 0.006 gm. of the salt employed, which became reduced to 0.001 gm. in three days. With 0.3 gm. of salt in 100 cc. it is necessary to add thirty times the weight of the acid of the salt in order to prevent any precipitation under similar conditions, but if the temperature be raised, precipitation ensues, and at 100° C. it is necessary to have 90 or 100 parts of free acid present in order to prevent precipitation of the sulphide. The results vary with all the conditions, and it would be incorrect to define a limit depending on the acidity of the solution, since the decomposition is a function not only of the relation of the weight of free acid to the weight of the solution, but also of the acid to metal.

—G. H. B.

On the Estimation of Manganese by Hydrogen Peroxide. A. Carnot. *Compt. Rend.* **107**, 1159.

The author rectifies an error in a previous communication (this Journal, 1889, 138) by stating that the precipitates yielded by his method are of the composition Mn_2O_{11} (or $5 MnO_2 + MnO$) and not the binoxide. Consequently 5 equivalents of oxygen correspond exactly to 6 equivalents of manganese.—G. H. B.

The Volumetric Determination of Sulphates. H. Quantin. *Bull. Soc. Chim.* **51**, 21—24.

This method depends on the reaction of sulphuric acid on barium chromate, by which chromic acid is liberated in a condition available for titration with a ferrous salt. The standard reagent is prepared by dissolving 19.48 grms. of neutral potassium chromate in 200 cc. of water and adding 50 to 100 cc. of hydrochloric acid; 24.35 grms. of barium chloride in solution are then added slowly with continual agitation, so as to redissolve the precipitate, and the whole diluted to 1 litre and filtered. 50 cc. of this solution are required for 0.3 or 0.4 gm. of sulphuric acid. To standardise this solution 1 gm. of pure dry potassium sulphate is dissolved in about 600 cc. of water, and 100 cc. of the chromate solution are added and shaken up. When the mixture begins to become clear, an excess of ammonia is added, and the whole diluted to 1 litre. 100 cc. of the filtered solution are then acidified with 5 cc. of pure sulphuric acid, and titrated with a standard ferrous sulphate solution, using potassium ferricyanide as indicator. The ferrous sulphate solution is prepared by dissolving 20 grms. of ferrous ammonium sulphate and 10 cc. of pure sulphuric acid in 1 litre of water. The amount of chromic acid thus found is the equivalent of the sulphuric acid which was added to the barium chromate solution, plus a small correction, which is due to the necessity for having a slight excess of chromic acid over the barium in the standard reagent. This correction is ascertained by a blank experiment. If, in making up the original solution, the barium chloride were in excess of the chromate, some barium sulphate would be precipitated in the subsequent operations without leaving its equivalent of chromic acid. The method gives very exact results.—G. H. B.

Critical Examinations of the Methods for Analysing the Raw Material for producing Tartaric Acid. Chem. Zeit. **13**, 160—161.

The article contains some observations on the methods of Goldenberg, Scheurer-Kestner, Fresenius, and Goldenberg-Geromont; and recommends the method of Goldenberg-Geromont as the best and most reliable one.—A. L.

Test for Nitrobenzene in the presence of Bitter Almond Oil. K. List. *Chem. Zeit.* **12**, 172—178.

If crushed almonds become strongly odorous after mixing with water, the smell of prussic acid is easily removed by warming with some carbonate of soda solution and some drops of a ferrous salt solution. After addition of potassium permanganate the smell of benzaldehyde also disappears. This treatment, has, however, no effect on nitrobenzene, which can thus be easily identified.—A. L.

Selection of Benzoyl Sulphonic imide (Saccharine) by the Fluorescein Reaction. E. Bornstein. *Ber.* **21**, 3396—3397.

This is a reply, the objection raised to the test being that resorcinol heated alone with concentrated sulphuric acid gives a green fluorescent substance (this Journal, 1888, 458). The great difference in intensity makes the test, however, according to the author, perfectly reliable; 1 mg. of the substance imparts a distinct fluorescence to 1 litre of water. The sulphonic imide, or substance containing it, is heated in a test tube with sulphuric acid, diluted, and caustic soda added. On addition of the alkali the sudden change to green is very characteristic, and is only given by phthalic anhydride and phthalimide.—J. B. C.

Detection of Colours on Dyed Wool. G. Dommergue. *Monit. Scient.* **33**, 25—40.

No methods have been published for detecting the coal tar colours on dyed wool; with the exception of the tests given by Rénard, which deal with these colours fixed on cotton, most of the literature relates to the detection of the natural dyestuffs. The analytical tests of O. Witt and E. Weingartner refer to the dyes in the free state and are inapplicable to dyed tissues, since when fixed they are insoluble in the majority of solvents ordinarily used in testing, such as water, alcohol, alkalis, and dilute acids.

Only such reagents as are used in the dyehouse are employed in the following tests.

REAGENTS.

Alkalis.—Ammonium hydrate, 21° B., normal potash corresponding to 100 grms. sulphuric acid per litre.

Acids.—Hydrochloric acid, 21° B., sulphuric acid, 66° B.

The tests are made by spotting with the several reagents the dyed fabric placed on a porcelain surface, or, if the shade be dark, the fabric is examined by looking through it towards the light.

PART I.

TESTING OF PURE SHADES.

Violet Colours.

Dahlia Violet (Imperial or phenylated violet, red shade).—Hydrochloride of monophenylosaniline.

Parma Violet (Imperial or phenylated violet, blue shade).—Hydrochloride of diphenylosaniline.

These violets, soluble in spirit, have been replaced by the methylosaniline violets.

Their reactions are as follows: NH_4OH , completely decolourises; KOH , red colouration; HCl , brown colouration; H_2SO_4 , orange colouration.

Methylor Paris Violet R.—Hydrochloride of monomethyl-p-rosaniline.

Methyl or Paris Violet B.—Hydrochloride of trimethyl-p-rosaniline.

Paris Violet, very blue.—Hydrochloride of pentamethyl-*p*-rosaniline.

Paris Violet N, Benzyl Violet, or Methyl Violet 5 B.—Hydrochloride of dimethylbenzyl-*p*-rosaniline.

Crystal Violet.—Hydrochloride of hexamethyl-*p*-rosaniline.

The reactions of this group are: NH_4OH , slowly decolourises; KOH , as with NH_4OH ; HCl , completely decolourises, tissue is coloured purplish-grey; H_2SO_4 , turns yellowish-brown.

Gallein or anthracene violet.—Pyrogallolphthalein.

This is largely used for dyeing fast shades.

NH_4OH , colour becomes paler; KOH , as with NH_4OH ; HCl , brownish-red colouration; H_2SO_4 , orange colouration. The ash usually contains chrome.

Blue Colours.

1. Triphenylmethane Compounds.

Bleu de Lyon (Spirit Blue, Paris Blue, Light Blue, Opal Blue).—Hydrochloride of triphenylrosaniline.

NH_4OH , completely decolourises; KOH , colour destroyed, tissue coloured greyish-pink; HCl , completely decolourises; H_2SO_4 , brownish-red colouration.

Nicholson's or Alkali Blues.—Sodium salts of triphenylrosaniline-sulphonic acids.

NH_4OH , completely decolourises; KOH , slowly decolourises, tissue coloured pink; HCl , colour becomes slightly green; H_2SO_4 , brownish-red colouration.

Victoria Blue B.—Hydrochloride of tetramethylphenyl-triamidodiphenyl-naphthylcarbinol—

NH_4OH , colour becomes slightly greyish; KOH , red colouration; HCl , orange-red colouration; H_2SO_4 , orange colouration.

Victoria Blue 4 R.—Hydrochloride of pentamethylphenyl-triamidodiphenyl-naphthylcarbinol—

NH_4OH , incompletely decolourises; KOH , decolourises, fibre coloured silver-grey; HCl , yellowish-brown colouration; H_2SO_4 , orange colouration.

II. Compound Blues.

The so-called indigo substitutes are mixtures of violets of more or less blue shade and of greens derived from triphenylmethane. The chief of these mixtures are: Acid green and acid violet R. or B, acid green and methyl violet, and methyl green and methyl violet.

Acid Green and Acid Violet R. or B.— NH_4OH or KOH , completely decolourises; HCl , brownish-red colouration; H_2SO_4 , brownish-yellow colouration.

Acid Green and Methyl Violet; Methyl Green and Methyl Violet.— NH_4OH or KOH , the green disappears entirely, the violet partly remains; HCl , brownish-yellow colouration; H_2SO_4 , as with HCl .

III. Indulines.

Fast Blue R. (B. A. S. F.).— NH_4OH , violet-grey colouration; KOH , violet-grey colouration; HCl and H_2SO_4 , little action.

New Blue (M. L. and P.).— NH_4OH or KOH , greyish-purple colouration; HCl or H_2SO_4 , bluish-violet colouration.

IV. Anthracene Colouring Matters.

Alizarin Blue S.—Sodium bisulphite compound of alizarin blue soluble in spirit.

NH_4OH , colour slowly becomes paler; KOH , colour paler and more green; HCl , little action; H_2SO_4 , little action.

The ash contains chrome.

V. Natural Colouring Matters.

Indigo.— NH_4OH , no action; KOH , no action; HCl , no action; H_2SO_4 , colour becomes very slightly greenish.

A small portion of the dyed tissue heated in a closed tube gives a violet vapour of indigotine.

The ash contains either iron or zinc according to the vat used.

Indigo Carmine and Sulphate.— NH_4OH , little action; KOH , yellow-brown colouration; HCl , little action; H_2SO_4 , violet-blue colouration.

A small portion of the dyed tissue heated in a closed tube does not evolve vapours of indigotine.

VI. Mineral Colouring Matters.

Prussian Blue. $\text{Fe}_4(\text{CN})_{12}$ deposited on the wool from an acid bath through the reducing action of the wool. NH_4OH , turns violet; KOH , fibre buff; HCl , colour rendered slightly paler; H_2SO_4 , yellow-brown colouration.

The ash contains iron, sometimes also alumina.

Green Colours.

1. Triphenylmethane Compounds.

Malachite Green (Victoria Green, Diamond Green).—Double chloride of zinc and tetramethyldiamidotriphenylcarbinol.

Light Green S. (Acid Green, Helvetia Green).—Sodium salt of tetramethyldiamidotriphenylcarbinol-sulphonic acid.

Brilliant Green (Solid or Fast Green, New Victoria Green).—Oxalate of tetramethyldiamidotriphenylcarbinol.

Methyl Green (Light Green).—Zinc double salt of methylhexamethylparosaniline. (Little used.)

NH_4OH , completely decolourised; KOH , as with NH_4OH ; HCl , yellow-brown colouration; H_2SO_4 , as with HCl .

Coccalein S.—Sodium bisulphite compound of coccalein soluble in spirit.

NH_4OH , becomes much paler; KOH , as with NH_4OH ; HCl , slowly becomes paler; H_2SO_4 , dull-red colouration.

The ash contains chrome.

Yellow and Orange Colours.

1. Nitro Compounds.

Picric Acid.—Trinitrophenol.

NH_4OH , little or no action; KOH , reddened slightly; HCl , slowly decolourised; H_2SO_4 , decolourised.

A small portion of the tissue moistened with potassium cyanide becomes coloured a rich reddish-brown, potassium isopurpurate being formed, tissues dyed with dinitroresol or naphthol yellow are decolourised by the same reagent.

Golden Yellow (Manchester Yellow).—Alkaline salt of dinitroresol.

NH_4OH , no action; KOH , slowly and imperfectly decolourised; HCl , decolourised; H_2SO_4 , decolourised.

Naphthol Yellow S.—Sodium salt of dinitro- α -naphthol sulphonic acid.

NH_4OH , no action; KOH , decolourised; HCl , slowly decolourised; H_2SO_4 , decolourised.

II. Azo-Compounds.

Orange 1 (Poirrier) (Tropacolin 000).—Sodium salt of α -naphtholazobenzenesulphonic acid.

NH_4OH , red colouration; KOH , violet colouration; HCl , violet colouration; H_2SO_4 , violet colouration.

Orange 2 (Poirrier) (Tropacolin 000 No. 2).—Sodium salt of β -naphtholazobenzenesulphonic acid.

Orange 3 (Poirrier) (Methyl Orange, Helianthine).—Sodium salt of dimethylanilineazobenzenesulphonic acid.

The reactions of these two dyes are the same.

NH_4OH , little or no action; KOH , red colouration; HCl , red colouration; H_2SO_4 , as with HCl .

Orange 4 (Poirrier) (Orange N., Diphenylamine Orange, Tropaeolin 00).—Sodium salt of diphenylaminazobenzene-sulphonic acid.

NH_4OH , little or no action; KOH , as with NH_4OH ; HCl , violet colouration; H_2SO_4 , as with HCl .

Indian Yellow (Monnet).—Nitro-compound of Orange 4. NH_4OH , little action; KOH , brown colouration; HCl , violet colouration; H_2SO_4 , as with HCl .

Fast Yellow R. (Badische).—Sodium salt of amidoazobenzene-disulphonic acid.

NH_4OH , little or no action; KOH , little or no action; HCl , red colouration; H_2SO_4 , yellow-brown colouration.

Chrysoin (Poirrier) (Resorcinol yellow, Tropaeoline R or O).—Sodium salt of resorcinolazobenzene-sulphonic acid.

NH_4OH , little or no action; KOH , red colouration; HCl , orange colouration; H_2SO_4 , as with HCl .

III. Anthracene Colouring Matters.

Alizarin Orange (Nitroalizarin).— β -nitroalizarin.

NH_4OH , becomes slightly paler; KOH , reddens slightly; HCl , becomes slightly paler; H_2SO_4 , almost decolourised.

The ash contains chrome.

IV. Natural Colouring Matters.

Fustic.— NH_4OH , little or no action; KOH , as with NH_4OH ; HCl , completely decolourised; H_2SO_4 , little action. The ash contains alumina.

Turmeric.—This dyestuff has almost disappeared from use. NH_4OH , orange colouration; KOH , as with NH_4OH ; HCl , brown-red colouration; H_2SO_4 , red, changing to dull grey. Ash contains alumina.

Red Colours.

1. Triphenylmethane Compounds.

Magenta.—Salt of triamidotriphenylcarbinol or of triamidodiphenyltolylcarbinol.

NH_4OH , slowly decolourised; KOH , completely decolourised; HCl , yellow-brown colouration; H_2SO_4 , as with HCl .

Acid Magenta (Magenta S.).—Sodium salt of rosaniline-trisulphonic acid.

NH_4OH , decolourised; KOH , decolourised; HCl , the shade becomes much more blue; H_2SO_4 , yellow-brown colouration.

II. Azo Compounds.

Bordeaux R or B (M. L. and B.).—Sodium salt of α -naphthylamine-azo- β -naphthol-disulphonic acid.

NH_4OH , little or no action; KOH , yellow-brown colouration; HCl , little or no action; H_2SO_4 , blue colouration.

Amaranth (M. L. and B.).—Sodium salt of α -naphthylamine-azo- β -naphthol-trisulphonic acid.

NH_4OH , little or no action; KOH , colour turned slightly grey; HCl , little or no action; H_2SO_4 , violet-blue colouration.

Ponceau 3 R (M. L. and B.).—Sodium salt of xylene-azo- β -naphthol-disulphonic acid.

NH_4OH , little or no action; KOH , brown colouration; HCl , little or no action; H_2SO_4 , crimson-red colouration.

Roccellin (Fast Red A).—Sodium salt of β -naphthol-azo-naphthalene sulphonic acid.

NH_4OH , becomes slightly paler; KOH , darkens and becomes rather more blue; HCl , as with KOH ; H_2SO_4 , violet colouration.

Orchil Substitute (Poirrier).—Sodium salt of nitraniline-azo- α -naphthylaminesulphonic acid.

NH_4OH , dirty-grey colouration; KOH , as with NH_4OH ; HCl , magenta-red colouration; H_2SO_4 , brown colouration. Useful colour for compound shades, largely used in France.

Eosin 1, Hortensia, Erythrosin, Phloxin B extra, Cyanosin, Rose Bengal.—All the resorcinol derivatives show the same reactions.

NH_4OH , little or no action; KOH , as with NH_4OH ; HCl , yellow-brown colouration; H_2SO_4 , as with HCl .

These dyes can be easily removed from the fibre by solvents, and exhibit a greenish-yellow fluorescence, particularly in alkaline solution.

III. Anthracene Colouring Matters.

Alizarin W. S. (B. A. S. F.).—Sodium salt of alizarin-sulphonic acid.

NH_4OH , violet colouration; KOH , as with NH_4OH ; HCl , becomes slightly paler; H_2SO_4 , little or no action.

The ash contains chrome or alumina.

IV. Natural Colouring Matters.

Of these the following are still used for dyeing red:—

Orchil (mainly used for maroons, &c.).

NH_4OH , violet colouration; KOH , as with NH_4OH ; HCl , little or no action; H_2SO_4 , darkens and becomes more blue; fibre is destroyed.

Ash contains alumina.

Ammoniacal Cochineal (very little used).

NH_4OH , slowly becomes violet; KOH , shade turns violet; HCl , decolourised; fibre coloured grey; H_2SO_4 , yellow-brown colouration.

The ash contains alumina.

Redwood (Brazilwood, &c.).—

NH_4OH , becomes slightly paler; KOH , as with NH_4OH ; HCl , as with NH_4OH , but to a less extent; H_2SO_4 , yellow-brown colouration.

The above colouring-matters represent those which are at the present time employed in dyeing, those colours which have been replaced or abandoned are omitted. All colours which will resist moistening with ammonia solution are considered as fast.

PART II.

TESTING OF COMPOUND SHADES.

Grenats.

Red is the predominating colour in grenat. Bright grenats test like a mixture of yellow and red; in examining the same, first moisten with hydrochloric acid and notice whether—

(1.) The shade turns yellow;

(2.) The shade becomes slightly bluer or violet.

In the first case the grenat is produced from magenta and golden yellow, this being the only yellow which is dyed in a neutral bath, and which does not precipitate the salts of rosaniline.

The second test may be produced by either—

(a.) Acid magenta and chrysoin or naphthol yellow, when the test is only rendered slightly blue by hydrochloric acid; or

(b.) Acid magenta and Orange 4 (or similar azo-orange or yellow), in which case hydrochloric acid turns the colour violet.

All bright grenats lose their red colour when moistened with ammonia, yellow remaining; the shades very rarely obtained with Bordeaux and Amaranth are not altered by ammonia, but become violet blue or blue when touched with sulphuric acid.

Maroons and Compound-red Shades.

The colour is moistened with ammonia, and it is observed whether—

(1.) The shade becomes green;

(2.) Only yellow remains;

(3.) The shade becomes paler.

In the first case acid magenta is present since it is soluble in alkalis; the blue (indigo) is fast. Test further by moistening with hydrochloric acid, the yellow becomes violet, indicating Orange 4 (or other azo-orange or yellow);

chrysoin and naphthol yellow are rendered slightly blue by this treatment.

The shades produced with Acid magenta, indigo, and Orange 4 are very commonly met with, the others more rarely.

In the second case where the yellow remains after testing with ammonia solution the presence of Acid green, Acid violet, and Acid magenta is shown; if Orange 4 is also present the shade becomes red-violet when moistened with hydrochloric acid.

In the third case the shade is fast, it may be either—

- (a.) Azo red, indigo, and Orange 4, when on moistening with hydrochloric acid it becomes slightly violet; if this acid does not change the shade chrysoin is present.
- (b.) Logwood, giving a red colouration to the acid when tested with hydrochloric acid, mixed with Orange 4 and 64 (M. L. and B.), the compound shade changing to violet-red or grenat.

Olives.

The tissue is moistened with ammonia when—

- (1.) Only yellow remains, acid green and acid violet are present, moisten with hydrochloric acid to test the yellow. The shade containing Orange 4 changes to grenat, if it contains chrysoin it becomes yellow-brown.
- (2.) The shade becomes slightly more blue, indigo present; test the yellow as in (1).

Dark Greens.

The tissue is moistened with ammonia—

- (1.) Only the yellow remains. Acid green and Acid violet, together with Naphthol yellow or picric acid, the yellow is not easily detected.
- (2.) The shade if changed becomes paler; moisten with hydrochloric acid and notice if—
 - (a.) The acid is coloured red, showing presence of logwood, and the shade becomes red or violet red; the yellow is fustic. The ash contains chrome.
 - (b.) The yellow is destroyed and blue remains, in which case indigo and Naphthol yellow or picric acid are present.

Dark Blues and Purples.

The fibre is moistened with ammonia, and it is noted whether—

- (1.) Complete decolourisation takes place;
- (2.) The red is removed leaving the blue;
- (3.) The shade becomes slightly paler.

In the first case Acid magenta, Acid green, and Acid violet are present.

The second reaction shows the presence of indigo, the red being Acid magenta.

The third reaction indicates an azo-red and indigo, when further tested by hydrochloric and sulphuric when the shade is not appreciably changed.

Shades obtained with logwood, indigo carmine, and Acid magenta or an azo-red are difficult to analyse; the logwood colours acid as previously mentioned, and the ash contains chrome.

Blacks.

All blacks on wool are dyed with logwood; on testing with acid the shade reddens. There are two kinds.

- (1.) Blacks dyed on iron or copper-iron mordants (the oxides of these metals being left in the ash), which rub off easily. This black is exceedingly rare.
- (2.) Blacks dyed on a chrome or copper chrome mordant (shown by the ash). This black is almost always employed.

Scarlets.

Cochineal scarlets are turned violet by potash whilst the artificial scarlets are turned yellow, moreover tin is found in the ash of the Cochineal scarlet.

Yellows, Oranges, &c.

See the first portion of this paper.

Mode Colours.

In testing for the very numerous range of colouring matters used in the production of these shades, the chief tests for orchil, Acid magenta, orchil substitute, azo-oranges, &c. must be carefully borne in mind.—E. B.

New Method of Examining Alcohol for Aldehyde.

C. Girard and X. Rocques. *Compt. Rend.* **107**, 1158—1159.

THE previous methods of testing commercial alcohols for small quantities of aldehyde and amyl alcohol are only qualitative, and they also fail in distinguishing between these two impurities. The authors have succeeded in overcoming these defects by the following method:—3 grms. of the hydrochloride of *m*-phenylenediamine are dissolved in 200 cc. of alcohol of 50°, and the solution boiled for half an hour with an inverted condenser; the liquid acquires a yellow colour. After cooling for half an hour the solution is shaken. If aldehyde be present the colour gradually deepens and acquires a fine green fluorescence, due to the action of the air. The liquid is then rapidly distilled until 125 cc. have passed over, when the distillate will be of 75° strength. The distillate is examined for amyl alcohol by Savalle's method, which consists in heating to 66° with an equal volume of sulphuric acid, producing a brown colouration, the depth of which can be compared with that given by known percentages of pure amyl alcohol in alcohol of 75°. The aldehyde compound remains almost entirely in the residue of the distillation, whilst the amyl alcohol passes over completely with the 125 cc. The quantity of aldehyde is estimated by the depth of colouration of the residual liquid.—G. H. B.

Determination of Sulphur in Coal. Brullé. *Monit. Scient.* 1889, 230.

THE author having had very considerable experience of estimating sulphur in coals, by projecting little by little an intimate mixture of 1 gm. of coal to 20 grms. of a mixture of equal parts of sodium carbonate and nitre into a platinum crucible raised to a red heat, has found that his results were uniformly too low. He attributes this to a part of the sulphur passing away as SO₂.

Another method consists in operating on the entire bulk of the mixture in a combustion tube, heated progressively from front to back. In presence of organic matter not very rich in carbon, combustion takes place gently, and the process yields excellent results. But in the case of coals in which carbon is present to an extent up to and exceeding 90 per cent., the combustion is too active. It would be possible to correct this by increasing the proportion of sodium carbonate; but then the length of the tube must be much augmented, and the subsequent treatment of the solution obtained with barium chloride takes place in presence of too great a quantity of dissolved saline matter. A simple modification of the first mode of operating has given results which are all that could be desired. Instead of making the combustion in a platinum crucible, a long platinum boat was used, about 3 decimetres long, 15 mm. wide, and 15 mm. deep. A ledge or rim running along each side of the boat allows of a cover or lid being fitted almost hermetically upon the same.

The mixture of sodium carbonate, potassium nitrate, and coal is distributed along the bottom of the boat. The mixture is then again covered with a thin layer of carbonate and nitrate with which a little powdered chlorate of potassium

is mixed. A little of the mixture is also equally placed over the interstices of the long lid or cover.

The apparatus thus arranged is conveyed into a combustion furnace, and heated progressively from one extremity to the other, till the mixture is brought to complete fusion.

The tube is then washed out with warm water, the solution treated with hydrochloric acid, and evaporated to dryness, to render any silica insoluble which had been formerly contained in the coal. Treatment with dilute hydrochloric acid and filtration follow, and finally treatment with barium chloride.

This method of operating gives one-third more sulphur than that found by the first method in the same samples of coal.—W. S.

Estimation of Mustard-oil in the seed of Cruciferae.

O. Förster. Landw. Versuchsstat. 1888, 204—214.
(Compare this Journal 1888, 854.)

25 grms. of seed or cake prepared from it is rubbed to a thin magma with water and placed in a 250 cc. flask, connected with an inverted condenser, the upper end of which is bent so as to dip a few millimeters below the surface of 50 cc. of alcohol saturated with ammonia, contained in a flask. After half an hour, steam is passed into the magma until the liquid in the upper flask amounts to about 200 cc., and after 12 hours standing, in the closed flask, this is transferred to a beaker, boiled, treated with coarse floccy precipitated mercuric oxide, and boiled and stirred for a few minutes. Sufficient potassium cyanide is now added to dissolve the excess of mercuric oxide and the mercurio-ammonium hydroxide. The mercuric sulphide is then collected on a tared filter, washed, dried, and weighed, the weight multiplied by 0.4266 gives the amount of mustard-oil decomposed.—D. A. L.

Analysis of Wool Oils. A. Horwitz. Dingl. Polyt. J. 271, 29—30.

THE oily lubricating materials used in the manufacture of woollen goods are emulsions composed of liquid fats suspended in aqueous alkaline solutions. These coming under the author's notice were usually mixtures of olive and cotton-seed oils with solutions of ammonia and soda. As commercial olive oil is often sophisticated with mineral, rosin, and drying oils, all having an adverse influence on the subsequent manufacturing processes, it is necessary to look for them qualitatively before proceeding with the quantitative analysis, which is conducted as follows:—

1.5 to 2.0 grms. of the material are weighed in a closed vessel and extracted for some hours, with frequent shaking, with ether-alcohol. The soda remains undissolved, is collected on a weighed filter, dried, and weighed; the filtrate is divided into two parts, one of which is evaporated to dryness, giving the fat, while the other is supersaturated with hydrochloric acid and precipitated with platonic chloride, and the ammonia determined by weighing the ammonium platonic chloride formed, or the platinum left on igniting it. The water and ammonia together are determined by drying another portion of the substance at 100°—120° C.

As an example of the composition of this material and an instance of the precision of the method, this analysis may be quoted:—

	Per Cent.
Fat	13.16
Soda	0.91
Ammonia	0.32
Water	84.45
	99.84

The last two constituents represent a *liquor ammoniac* of sp. gr. 0.9983, which was probably used as such in the manufacture.—B. B.

On the Determination of Neutral Fat. M. Gröger. Zeits. f. angew. Chem. 1889, 61—62.

THE author has found that in saponifying cocoa-nut oil, olive-kernel oil, and palm oil for the determination of their saturation equivalents, it is necessary to have present an excess of alkali corresponding to at least 3 cc. of semi-normal acid, as otherwise they do not consume as much as they are capable of neutralising if this condition obtain.

For example a cocoa-nut oil which when saponified with so much alcoholic potash as to require the addition of 0.1 cc. of semi-normal hydrochloric acid to restore neutrality, gave figures corresponding to the presence of 91.9 per cent. of neutral fat, whereas when the excess of alkali was such as to use up 2.95 per cent. of the acid in backward titration, the true value 94.6 per cent. was obtained. That the higher value is correct is shown by the fact that when once the limit mentioned above has been exceeded, further excess of alkali is without effect on the results.—B. B.

Determination of the Quantity of Alkaloid in Zenbane Extract (Hyoscyamine). L. van Itallie. Nederl. Tijdschr. Pharm. Chem. en Toxikol. 1839, 1, 6.

ACIDIFY 5 grms. of the extract with 10 drops of dilute sulphuric acid (1:20), dilute with water to 50 cc., and macerate for 1—2 hours. Add 25 cc. of a 10 per cent solution of lead acetate, and allow to settle. Filter off 50 cc. of the solution through a dry filter paper, add 10 cc. of dilute sulphuric acid (1:10) to the filtrate and again filter off 50 cc. Transfer this second filtrate to a separating funnel, add ammonia to alkaline reaction and extract three times with an equal volume of chloroform. Separate the chloroform extract, distil off the chloroform, dissolve the residue in 5 cc. of dilute alcohol and titrate with centinormal acid. This method may also be applied for the quantitative examination of belladonna and aconite extracts.—C. A. K.

Red Lead. A. Kremel. Pharm. Pest. 1889, 22, 22.

To test red lead for mineral impurities 5 grms. are dissolved in 50 grms. of dilute nitric acid and 1 gm. of oxalic acid added; the insoluble residue should not weigh more than 0.05 gm.—C. A. K.

Red Lead. R. Frühling. Zeits. f. angew. Chem. 1889, 67—78.

See under XIII. page 203.

Determination of Nitric-Nitrogen by Kjeldahl's Method. O. Foerster. Chem. Zeit. 13, 229.

THE author has found the following modification gives good results. The nitrate (about 0.5 gm.) is treated with 15 cc. of phenol-sulphuric acid (6 per cent.), and after it

is dissolved, 1—2 gm. of sodium thiosulphate is added; thereupon, after the decomposition has taken place, 10 cc. of sulphuric acid and the requisite quantity of mercury are added. Sodium thiosulphate is recommended because thereby nitrosylsulphuric acid is formed, from which a loss of nitrogen as nitric oxide need not be feared. Of 14 determinations with pure potassium nitrate, the highest result obtained was 13.91 per cent. of N, and the lowest 13.79 per cent. The author recommends the absorption tube shown in the accompanying sketch, in which the bulbs A have a capacity of about 200 cc.—J. W. L.

Estimation of Benzene in Coal Gas. M. Berthelot. Bull. Soc. Chim. 1888, 660—662.

THE author determines the quantity of benzene in coal gas by introducing into the gas measured over water about 1 cc. of fuming nitric acid contained in a small flask of 20 to 25 cc. and shaking up for about half a minute at the outside and reading off the loss of volume. The action of the nitric acid must not be protracted longer, as the other hydrocarbons, such as acetylene, the olefines, and carbon monoxide may also be attacked. Further details are given in a previous paper (Bull. Soc. Chim. 1888, 171). (See also this Journal, 1889, 61.)—J. B. C.

New Books.

DIE CHEMIE DES STEINKOULENTHEERS MIT BESONDERER BERÜCKSICHTIGUNG DER KÜNSTLICHEN ORGANISCHEN FARBSTOFFE. VON GUSTAV SCHULTZ. Zweite Vollständige Aufgearbeitete Auflage. Zweiter Band. Die Farbstoffe. Dritte Lieferung. 1889. Braunschweig: Druck und Verlag von Friedrich Vieweg und Sohn. London: H. Grevel and Co., 33, King Street, Covent Garden.

IS this Part (the Third), Chapter XXXII, is continued and completed. It deals with Magenta and its Sulphonic Acids. Chapter XXXIII, treats of the Alkyl- and Phenyl-derivatives of Magenta and their Sulphonic Acids, and also of the corresponding Naphthyl compounds. Of course, under these are comprised—(1.) Violet Colouring matters; (2.) Blue Colouring matters; and (3.) Green Colouring matters of the Pararosamine and Rosaniline series. In Chapter XXXIV, are to be found the Phenyl- and Toly-derivatives of the Rosanilines, also the Sulphonic Acids of Triphenylrosaniline, and, finally, Toluidine Blue. Aurin and Rosolic Acid and their derivatives find very complete treatment in Chapter XXXV, and when Chapter XXXVI, is reached, we find a most comprehensive monograph on the Phthaleins, Eosines and Substituted Eosines, under which the new colour Rhodamine appears. Owing to the singular beauty and unique tints produced by this dye, on silks more especially, the original compound has gone through such a series of metamorphoses through substitution, that the Rhodamines are now found to comprise quite a special class of compounds. The volume commences with page 355 and ends on page 576, and it contains three woodcuts.

THE CHEMICAL ANALYSIS OF IRON. A complete account of all the best known Methods for the Analysis of Iron, Steel, Pig-Iron, Iron-Ore, Limestone, Slag, Clay, Sand, Coal, Coke, and Furnace and Producer Gases. By ANDREW ALEXANDER BLAIR, Graduate United States Naval Academy, 1866; Chief Chemist United States Board, appointed to Test Iron, Steel, and other Metals, 1875; Chief Chemist United States Geological Survey and Tenth Census, 1880. London: Whitaker and Co., White Hart Street, Paternoster Square. Philadelphia: J. B. Lippincott, 1888.

THIS is an 8vo. volume bound in cloth, containing 274 pages of subject-matter and an alphabetical index. The text is embellished with 94 wood engravings, and the work terminates with some useful tables. In opening the subject it will be noticed that a few pages are devoted to a matter of which most works on Chemical Analysis are quite oblivious, and yet without due attention to which Commercial Analyses are of little or absolutely no value—this is the subject of Sampling and Apparatus for preparing the Samples. Next comes the subject of Reagents, and then Methods of Analysing Pig-Iron, Bar-Iron and Steel; Determinations of Silicon, Slag and Oxides; Phosphorus; Manganese; Carbon, graphitic and combined; Titanium; Copper; Nickel and Cobalt; Chromium and Aluminium; Arsenic; Antimony; Tin; Tungsten and Vanadium; Methods for the Analyses of Iron Ores, Limestones, Clays, Slags, Fire-sands, Coal and Coke, and Gases. The whole subject appears to receive very complete treatment, for under the principal headings we find, *e.g.*, (1.) Methods of Collecting the Samples; (2.) Preparation of Reagents; and (3.) Methods of Analysis. Further, the text is spaced off and rendered easy of reference by a kind of concurrent index of the various paragraphs in small type.

PRACTICAL ORGANIC CHEMISTRY. The Detection and Properties of some of the more Important Organic Compounds. By SAMUEL RIDEAL, D.Sc. (Lond.), F.C.S., F.I.C., Fellow of University College, London. London: H. K. Lewis, 136, Gower Street, 1889.

SMALL 8vo volume, bound in cloth, containing Preface, Table of Contents, Introduction, 155 pages of subject-matter, a couple of pages devoted to the "Order of Analysis," and an Alphabetical Index. The work is grouped as follows:—The Organic Acids; the Carbohydrates; the Organic Bases, and Neutral Substances. The work may be briefly defined as a small manual of Qualitative Organic Chemistry more especially suited for the Medical Student in his higher examinations, as well as for the student who reads for the London University B.Sc. and Int. M.B. Examinations.

Trade Report.

(From the Board of Trade Journal and other sources.)

TARIFF CHANGES AND CUSTOMS REGULATIONS.

THE NETHERLANDS.

Customs Classification of Antipyrine.

According to the *Moniteur Belge* for the 1st February last, the Netherlands Customs authorities have decided that antipyrine is free from import duty, whatever may be the nature of the package in which it is imported.

FRANCE.

Recent Customs Decisions.

Note.—Kilog. = 2·204 lbs. avoirdupois. Franc = 94 $\frac{1}{2}$ d.
Hectolitre = 22 imp. gallons.

A report, dated the 1st February last, has been received from Mr. J. A. Crowe, Her Majesty's Commercial Attaché at Paris, enclosing copies of circulars recently issued by the French Customs Department, respecting the classification of articles in the Customs Tariff and the application of the Customs law of France.

Circular No. 932 withdraws the privilege hitherto granted to importers of lard mixed with less than 25 per cent. of cotton oil to pay duty on the mixture in proportion only to the weight of the oil. From the 1st of May next, lard mixed with any quantity of cotton oil will be charged 6 francs per 100 kilos., like pure vegetable oils (*antres*).

Circular No. 934 reduces the number of volatile essences requiring certificates of origin to 10, viz.: Essences of bitter almonds, cinnamon, cloves, bergamot, lemon of Portugal, lavender, thyme, *bigarade*, mint, and marjoram.

Circular No. 1357 requires that importers should distinguish in their declarations between vinegar made from wine or pyrogenous acid and vinegar derived from an alcoholic base. The latter will not only be charged with the ordinary Excise and Customs due leviable on vinegar, but with a "duty of denaturation" of 37 francs per hectolitre.

SWITZERLAND.

Classification of Articles in Customs Tariff.

Compressed sulphurous acid, in cylinders of wrought iron.—Category 9a. Duty 7 frs. per quintal (220 $\frac{1}{2}$ lbs. avoirdupois).

GREECE.

Modifications in Customs Tariff.

Note.—Drachme = 94 $\frac{1}{2}$ d. Oke = 2·8 lbs. avoirdupois.

The following are extracted from a translation of a law sanctioned by the King of Greece on the 14th February, introducing modifications into the General Greek Tariff in accordance with the annexed table:—

No. in Tariff.	Classification of Articles.	General Import Duty.	
		Oke	Dr. Lep.
11c	Madder seed.....	Oke	0 10
88a	Varnish prepared with oil and boiled linseed oil.....	"	0 30
88b	Varnish prepared in alcohol.....	"	0 70
94	Starch.....	"	0 20
90	Kerosine, paraffin, or other artificial wax	"	1 00
103a	Potash, carbonate of soda, caustic soda used in soap making and glass making, as well as saltpetre for gunpowder making and carbonate of sulphur.....	Free.	
136	Molasses.....	Oke	0 25
137	Sugar, glucose, syrups, and honey.....	"	0 75

UNITED STATES.

Customs Decisions.

The following decisions affecting the classification of articles in the Customs Tariff have recently been given by the United States Customs authorities:—

An article designated as albumen-substitute or glue-paste, which is a compound of albumen, glue, and a hydrocarbon, resembling spirits of turpentine, is dutiable under section 2513 of the Revised Statutes as an unenumerated manufactured article, at the rate of 20 per cent. *ad valorem*.

So-called valerianic ether (valerianate of amyl) is dutiable as a fruit-ether under T. L. 114.

So-called soda-lime, which is a union of two compounds (caustic lime and caustic soda), and is prepared principally for laboratory purposes, is dutiable as a chemical compound under T. L. 92.

An article variously styled "parchment paper," "parchmentised paper," "vegetable parchment," "papyrine," &c., but which, it appears, is in reality paper which has been subjected to a process or treatment to fit it for use with machinery in a manner similar to that for which animal parchment is used, is held not to be a manufacture of paper, under T. L. 388, but to be dutiable as paper not otherwise enumerated under T. L. 392.

An importation of stearine, claimed to be free of duty as an "acid used for manufacturing purposes," was held to be dutiable, under the provisions of section 2513 of the Revised Statutes, as an unenumerated manufactured article, at the rate of 20 per cent. *ad valorem*.

A composition of glue and other substances adapted and intended for use in applying and fixing gold or bronze to paper-hangings, and which is commercially known as "gold-size," is held to be free of duty, under the provision in the free list, T. L. 711, for "gold-size."

An article claimed to be annatto extract, but found upon analysis to consist of water (81.31 per cent.), organic colouring matter, coal-tar colour (13.64 per cent.), and inorganic matter, alumina, &c. (2.02 per cent.), which combination constitutes a lake, is held to be dutiable at the rate prescribed by T. L. 87, for "colours and paints, including lakes."

Oils, cassia, orange, and attar of roses are held to be dutiable as expressed oils under T. L. 92.

"Liquor ammonia odoriferous" is held to be dutiable as a proprietary preparation under T. L. 96.

PERU.

Changes in the Customs Tariff.

The following articles are declared free of import duties:—

Tar; quicksilver; Roman cement; tanner's bark; crucibles; dynamite; gunpowder and other explosives for mining; matches; detonators; chemicals for purifying wine, excepting those of an injurious character; poison for tanning.

CUSTOMS TARIFF OF FIJI.

The following are extracted from a statement of the rates of import duty now levied under the Customs Tariff of Fiji:—

Classification of Articles.	Rates of Duty now levied.
Blue.....	Lb. £ s. d. 0 0 2
Blacking.....	10 % <i>ad val.</i>
Baking powder.....	10 % <i>ad val.</i>
Candles.....	Lb. 0 0 1
Cement.....	10 % <i>ad val.</i>
Dynamine and lithofracteur.....	Lb. 0 0 6
Drugs, including all articles of the kind and form used as medicines.....	15 % <i>ad val.</i>
Earthenware.....	10 % <i>ad val.</i>
Fuse.....	10 % <i>ad val.</i>
Glass and glassware.....	10 % <i>ad val.</i>
Gelatin.....	Lb. 0 0 3
Glue.....	10 % <i>ad val.</i>
Gutta-percha and india-rubber.....	10 % <i>ad val.</i>
Ink.....	10 % <i>ad val.</i>
Kerosene (of not less than 150° test).....	Gallon 0 0 9
Kerosene, all other tests.....	" 0 1 3
Leather.....	10 % <i>ad val.</i>
Methylated spirits.....	Gallon 0 2 0
Matches.....	10 % <i>ad val.</i>

Classification of Articles.

Rates of Duty now levied.

Opium and all preparations thereof.....	Lb. £ s. d. 0 15 0
Oils of all kinds (except medicinal).....	Gallon 0 0 9
Powder (sporting).....	Lb. 0 0 6
Paints, wet or dry.....	10 % <i>ad val.</i>
Perfumery.....	15 % <i>ad val.</i>
Soap (hard and soft).....	Lb. 0 0 1
Soap (fancy, scented, or medicated).....	15 % <i>ad val.</i>
Salt and saltpetre.....	Ton 1 0 0
Soda (crystals).....	" 1 0 0
Turpentine.....	Gallon 0 1 0
Varnish.....	" 0 2 0
Vinegar (in bulk or bottle).....	" 0 0 6

The following articles are free:—Mannres, pitch, powder (blasting), resin, sulphur, and tar.

A general duty of 5 per cent. *ad valorem* is charged on all articles not specified or not included in the free list.

An export duty of 5% per ton is charged on sandalwood, manufactured or unmanufactured.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

TRADE OF FRANCE WITH TUNIS IN 1888.

Mr. J. A. Crowe, Her Majesty's Commercial Attaché at Paris, states that imports from Tunis into France rose from 5,440,039 francs in 1887 to 7,247,754 francs in 1888, and that it is mainly due to an increase of 1,222,850 francs in the value of the trade in olive oil. More wool, too, has been sent to France as well as more wax.

In about the same ratio as the imports into France improved, those of France into Tunis declined, and among the chief decreases were spirits, chemicals, and soap.

FIJI ISLANDS.

Drug Imports.

Fiji imported, in 1887, 188,071l. worth of goods, nearly half of which came from New South Wales, and a considerable proportion from New Zealand and Victoria, which are gaining rapidly at the expense of New South Wales; the United Kingdom contributing about 12 per cent. to the direct trade. The imports include:—

	1884.	1885.	1886.	1887.
Drugs.....	£ 5,286	£ 3,840	£ 2,530	£ 2,088
Soap.....	2,463	2,344	1,765	1,715
Oils and oil stores.....	10,497	8,974	7,811	7,954
Paints.....	2,284	1,077	1,030	1,174

SPAIN.

Olive Oil in Malaga.

The cultivation of the olive in the Malaga district is declining, not so much owing to the failure of the last two crops as to the backward nature of the processes in use for extracting the oil. Improvements in this respect have been limited to the substitution of iron for stone rolls, and screw or hydraulic presses for the traditional wooden beam, which some of the farmers still continue to use. These improvements have had for their object merely an increase in the quantity of the oil by exercising greater pressure on the olive, but very little attention has been given to improving the quality. This is especially to be regretted, as the coarser kinds of olive oil are now being supplanted by seed oils and petroleum—the latter being used for lamps, the former for lubricating machinery and the manufacture of soap. Hence the oil trade of Malaga is undergoing a severe crisis, and the price of olive oil, which used to range between 9s. and 9s. 2½d. the "arobe" (25 lbs.), has now fallen to between 6s. and 7s. The trade in oils is likewise hampered by the exorbitant railway tariffs, which considerably impeded its transportation by land.—*Chemist and Druggist*.

TURKEY IN EUROPE.

Drugs in Constantinople.

Nearly all chemicals sold in Constantinople, says the Austrian Consul, are of German manufacture, a few specialties and also quinine being bought from Milan. In drugs, the principal trade is done by London, Marseilles, Genoa, and Hamburg. Pharmaceutical preparations are partly supplied by France, but some of the large German factories have been able lately to find a large share of the trade formerly done by the French.

Terms.—Drugs are always bought "c.i.f. Constantinople," chemicals, &c., delivered at Trieste or Marseilles. Great Britain sells almost exclusively on cash terms, France gives three to four months' credit, but German, Austrian, and Italian dealers must generally allow from four to five months' credit.

—*Chemist and Druggist.*

UNITED STATES OF COLOMBIA.

Coca.

Scarcely any plant cultivated in Colombia can be said to be confined exclusively to the temperate zone, except perhaps coca, which, however, is now little grown. It is only in general use as an article of daily consumption in the south of the department of Cauca, where it is the custom to hire labourers at so many reals a day and so much coca. But it is grown in small quantities in several parts of the country, and used mostly by Indians. It is also sold for medicinal purposes in the markets of most of the large towns. At the time of the Spanish conquest it was general all over the country, but the use of it gradually died out. The recent demand for coca for the extraction of cocaine does not seem to have stimulated its cultivation in any part of the country. About 1,000 lbs. were exported in 1887.

Eucalyptus.

Eucalyptus trees have been largely planted during the last 20 years in many parts of the country, especially on the savana of Bogotá. The *E. Globulus* is the species which has been most planted, though others, such as the *E. citriodora*, *E. rostrata*, and *E. saligna*, have been tried. Many attempts have been made to introduce some species of the tree into very hot districts, such as Carthagena and some parts of the Magdalena valley, but so far without success.—*Chemist and Druggist.*

EXTRACTS FROM THE REPORT OF THE UNITED STATES CONSUL AT BUENOS AYRES ON THE INDUSTRIES AND COMMERCE, &c. OF THE ARGENTINE REPUBLIC.

An increased impulse is noted in every department of trade and industry, and the Consul thinks that, in spite of the minor impediments of bad financial management and a persistent disregard of the laws of trade, the movement is not fictitious, but genuine.

New industries are cropping out in all directions, and all classes of the people are aroused to the possibilities of the new departure. On the other hand the constantly increasing volume of irredeemable currency and the continuance of the suspension of specie payments make it only too easy to float the most extravagant schemes, and many are being carried beyond the bounds of prudence into speculation. At the same time there is greater confidence in the stability of the institutions of the country, and accordingly both capital and labour are flowing into the country.

According to official returns, 128,797 immigrants arrived during 11 months of 1888, as against 137,426 for all 1887, and 93,116 for 1886. The Consul does not recommend it as a field for immigration for English-speaking peoples accustomed to a higher plane of civilisation, but considers it most suitable for immigrants from the shores of the Mediterranean, who are similar to the people of the country in language and habits, and soon assimilate with the native population.

The Consul, after treating of the railway and maritime facilities offered, proceeds to treat of the internal commerce and agriculture of the Republic. Under this last head he mentions that the shipments of crop products in 1887 were as follows, and gives the shipments for 1882 for the sake of comparison:—

Articles.	1882.	1887.
	Tons.	Tons.
Wheat.....	1,705	237,865
Flour	548	5,401
Indian corn.....	167,327	361,844
Linseed.....	23,351	81,208
Barley.....	1,100	4,194
Peanuts.....	422	3,367

He considers that, owing to bad weather, the exports for 1888 will show a decrease. Of the above exports the linseed nearly all goes to England, and the peanuts to France for the manufacture of olive oil.

The following are the shipments of metals and minerals for 1887 and first nine months of 1888:

Principal Articles.	1887.		First nine Months of 1888.	
	Kilos.	Value.	Kilos.	Value.
		Dollars.		Dollars.
Copper in bars..	143,287	57,315	115,770	46,308
Copper mineral .	4,110	1,644	262,622	48,250
Silver mineral ..	106,780	53,090	321,000	161,660
Lead ore.....	156,386	12,544	96,316	7,706
Silver, pure.....	1,630	61,753	12,837	447,969
Gold dust.....	325,524*	55,101
Bismuth	35,072	140,288
Tin	301,835	159,818
Silver metal	11,070	110,700
Total Value.	..	186,356	..	1,195,137

* The figures for gold dust must be erroneous.

The gold referred to above is believed to be the product of recent mining operations in Tierra del Fuego.

The Consul believes that there are immense deposits of other valuable metals besides gold in various parts of the Argentine Republic, but to develop them will, in his opinion, require careful scientific investigation into the geology of the country. Coal has been discovered, but, so far, has not been utilised; and enormous petroleum reservoirs occur in the provinces of Mendoza, Salta, and Jujuy, but thus far, notwithstanding a high protective duty, no oil has been placed upon the market.

Foreign Commerce of the Argentine Republic.

Commerce.	1886.	1887.	Increase.
	Dollars.	Dollars.	Dollars.
Imports	95,408,715	117,352,125	21,943,380
Exports	69,834,841	84,421,820	14,586,979
Total	165,243,586	201,773,945	36,530,359

Commerce is conducted mainly through the ports of Buenos Ayres and Rosario, and was distributed as follows in 1887:—

Countries.	Imports.	Exports.	Total.
	Dollars.	Dollars.	Dollars.
Germany	12,108,456	9,835,754	21,944,210
Belgium	10,947,955	12,111,531	23,059,486
United States....	11,004,553	5,938,808	16,943,361
France	22,743,550	24,871,354	47,614,904
Italy.....	7,937,741	3,167,113	10,144,854
Great Britain....	34,779,219	17,085,061	51,864,220

The imports for 1887 as compared with 1886 have increased from the following countries:—

Countries.	Increase.	Countries.	Increase.
	Dollars.		Dollars.
Germany	2,063,581	France	5,741,512
Belgium	3,226,038	Italy	2,390,501
United States	3,331,269	Great Britain	1,316,559

The exports in the same period have increased to:—

Countries.	Increase.	Countries.	Increase.
	Dollars.		Dollars.
Germany	3,884,846	France	2,520,171
Belgium	1,186,794	Italy	630,675

The imports of drugs and chemicals in 1887 showed an increase of 481,983 dols. over those of 1886.

Speaking of imports generally the Consul considers them "out of all proportion to a healthy condition of trade." The country is persistently buying more than it sells, and meets the difference by sending abroad the gold which its Government borrows.

It is true that the trade returns do show a large increase of exports. In 1887 they were 14,586,979 dols. greater than 1886, or an increase of 20 per cent.; but until there is a very decided increase in them, or a decrease in the imports, the commerce of the country cannot be said to be in a safe condition.

Argentine Trade with Great Britain.

If the trade with France shows a remarkable progression, that with England presents a still more surprising increase. In the last eight years it has more than triplicated, since from 17,272,193 dol., in 1880 it has reached to 51,864,229 do's. in 1887. In 1880 the imports from Great Britain amounted to only 12,103,660 dol.; in 1887 they were 34,779,211 dol.; in 1880 the exports to Great Britain were 5,168,732 dol.; in 1887 they were 17,085,001 dol. The imports from Great Britain were as follows:—

Articles.	Value.
	Dollars.
Live stock.....	200,160
Groceries and comestibles	1,297,330
Liquors.....	476,556
Woven goods	12,505,481
Ready-made clothing.....	2,150,635
Chemicals and drugs	1,227,134
Furniture	227,587
Paper.....	328,800
Boots and shoes	304,518
Iron and iron utensils.....	10,088,224
Jewellery, &c.....	515,717
Glass and crockery ware	860,515
Stone coal.....	3,854,422
All other imports.....	762,620
Total Imports	34,779,219

The exports to Great Britain comprised the following articles:—

Articles.	Value.
	Dollars.
Sheep skins	590,366
Salted ox hides	1,081,990
Wool, unwashed	500,024
Linseed (62,974,984 kilos.)	3,148,749
Indian corn (177,769,044 kilos.)	3,555,382
Wheat (143,947,643 kilos.)	5,837,906
Bones and bone-ash	243,219
Salt beef	401,558
Frozen mutton	838,702
Flour	28,769
Grease and tallow	273,196
Precious woods	82,928
Copper and silver ore	97,572
All other exports	390,867
Total Exports.....	17,085,001

It will be seen, from this table, that the surplus agricultural products of the country are beginning to find a market in England in such quantities as to cause no inconsiderable increase in the amount of exports to that country.

Imports of Chemicals and Drugs from the United States into Argentine Republic in 1887.

The Consul considers that the establishment of American sample houses has contributed not a little to swell the trade with the United States, but thinks that more could be done.

The trade returns for the first nine months of 1888 show an excess of imports over exports of 33,604,846 dol., which is more than the total excess of any previous year, but the excess consists almost entirely of liquors, fine clothing, and objects of luxury.

The Consul concludes with a detailed account of the finances and prospects of the country in which on the whole he takes a favourable view of the future.

MISCELLANEOUS TRADE NOTICES.

PRODUCTION OF QUICKSILVER IN RUSSIA.

La Nature points out that quicksilver was discovered in Russia in 1879, close to Nikitowka. In 1885 a company was established to work a mine, and this company began its labours in 1886. During the first year, 1887, the mine produced 3,911 pounds of mercury, that is to say, 64,966 kilos. It is estimated that the whole quantity of ore in the mine amounts to about 12 millions of pounds, of which 1·2 per cent. is mercury.

PRODUCTION OF METALS IN RUSSIA.

The *Gazette de Moscou* states that, according to a report recently issued by the Russian Administration of Mines to the Government, there were extracted in 1886 in Russia 1,720 pounds of fine gold, 263½ pounds of platinum, and 279,056 pounds of copper.

FOOD ANALYSIS IN ST. PETERSBURG.

The Russian *Nouveau Temps* states that two hygienic laboratories have been opened recently in the busiest parts of St. Petersburg, at which gratuitous analyses are made at any time of specimens of the following articles of consumption:—Drinking water, milk, flour, bread, meat, wine, beer, and kvass. What is offered in these laboratories is merely a general opinion as to whether foreign substances occur in the articles submitted, and whether the latter are fresh or not.

MANGANESE DEPOSITS IN TRANSCAUCASIA.

The *Revue Commerciale et Industrielle du Caucase* for the 15th (27th) January last, says that the persons working the deposits of manganese in Transcaucasia have for a long time solicited the aid of the Government for the construction of a branch railway between Kvirila and Tchihtoury. In the Chorapan district, and in the basin of the Kvirila, the beds occupy an area of 126 square versts (verste = 663 of a mile). The workings have been begun on both banks of the river in the neighbourhood of the villages of Rgami, Zéda-Rgami, Gvimevi, Perévissi, Choukrouty, and Itkhivissi. The manganese, carried with great difficulty on the backs of horses, mules, and by *arabes*, to the Kvirila station, is from there sent to Poti or Batoum.

Professor Kotsovsky, who was sent in 1886 by the Administration of Mines to Transcaucasia in order to examine the deposits of manganese there, has just published the results of his mission, and the following are his conclusions with respect to the projected railway:—

1. Notwithstanding the wealth of the Tchihtoury beds, they cannot be considered as being remarkable. In the Caucasus beds of manganese, having an area of 18 versts and containing more than 55 per cent. of metal, have been discovered.

2. As regards quality, the Tchihtoury ore is exposed to the competition of the ores of America, Spain, Caucasia, and deposits discovered in the Government of Catherineopol. According to analyses made, the Tchihtoury ore contains 55 per cent. of manganese; that of the environs of Tiflis, 60.34 per cent.; of Adjameti, 49.60 per cent.; of Novo-Souaki, 54 per cent.; of Tiflis, 48.72 per cent.; of Koukass, 49.48 per cent.; of Mexico and Chili, 55 per cent.; of Spain, 50.55 per cent.; and of Sweden, 47.20 per cent.

3. The manganese industry is profitable both for the owners of the deposits and for the contractors.

4. Although a brilliant future awaits the manganese industry, the construction of a railway with Government assistance does not appear to me at the present moment opportune.

5. A railway would not put a stop to the abuses committed by the contractors for the carrying of the ore.

6. A railway will not contribute to the improvement of the manganese industry until a better system for working the deposits is adopted.

7. The construction of a road is the only practicable means which may be recommended. With a good route, from 10 to 12 copecks per pound of ore will be saved in transport.

8. A system of control over the manganese industry in Transcaucasia and Caucasia should be organised.

9. The contractors and manufacturers who work the manganese deposits have a net profit of from 3 to 6 copecks per pound of ore, and the merchants who purchase the ore at the station of Kvirila gain in their turn 11 copecks per pound.

BRAZILIAN INDIA-RUBBER.

The journal *Le Brésil* states that during 1887 Brazil exported 15 million kilos. of india-rubber. The supply was abundant in 1888, but there is more than 15 million reis difference between the price obtained by sales last year and the year before. On account of the difficulties thus raised, the price of cocoa has also fallen, and that article now with difficulty fetches 400 reis, where last year it was sold for 500 reis. The amount of india-rubber produced in Brazil of late years may be seen from the following statement:—

Kilos.

1883-84	10,463,000
1884-85	11,885,000
1885-86	12,835,000
1886-87	13,395,000
1887-88	15,766,000

The largest quantity came from the province of Para.

COCOA NUT OIL IN CUBA.

We learn from *La Nature* that a special industry, and one which seems likely to enjoy a certain amount of success in the future, has been started at Baracoa in Cuba by a Frenchman. This is the manufacture of cocoa nut oil. According to a report which has been made by M. de Bérad, the French Consul at Santiago de Cuba, this factory has been fitted up with the latest inventions in the way of machinery for producing an oil of absolute purity. The cocoa oil, besides its medicinal properties, is useful as a lubricant, and as material for the manufacture of soap. It can also be employed for lighting. The refined cocoa oil is more economical than most other mineral and vegetable oils. It is very fluid and does not easily turn rancid.

EXPERIMENTAL CULTIVATION OF MYROBALANS IN SOUTH AUSTRALIA.

The *Adelaide Observer* for the 29th December last states that the South Australian Forest Department intend to plant seeds of myrobalans of commerce, which have been received from India, with a view of ascertaining whether they can be cultivated in the colony. The plant is used in dyeing cloth and leather.

THE AGRICULTURAL AND INDUSTRIAL CONDITION OF GUATEMALA.

THE TRADE OF BENGAL IN 1887—88.

See Board of Trade Journal for March, p. 355.

INDIA-RUBBER IN BURMAH.

The requirements for india-rubber being now so large, it is satisfactory to know that the india-rubber trade on the Chindwin, in Burma, although it has only existed for about a year, has increased to such an extent that the local government has placed a large export duty on all rubber passing Kendat, the first revenue station on the way to the seaports, besides imposing a licence costing ten rupees per annum on all brokers or buyers of the article. According to a recent report, rubber is extracted from the *ficus elastica*, which is similar in appearance to the banyan tree, except that the leaves are larger and of a darker colour. Each tree is tapped daily during the season, which extends from November to June, nothing being done during the remainder of the year. In April 1887 a Chinese syndicate at Bhamo received a monopoly for the extraction of rubber in the Mogong district. This expired last October, and since then the trade has been thrown open to all. On the Chindwin the trade is in the hands of an English company, which, in spite of vigorous opposition from the Chinese traders, is working satisfactorily, because the natives prefer dealing with the Europeans. All the transport is carried on by native boats down the Chindwin to Kendat, where the rubber is transhipped into steamers. The system of collecting is to send a contractor with a sum of ready money to all the villages in a particular district to make advances to the headmen, who, in their turn, send the villagers to the forests to extract the rubber, so that month by month each station has its own stock. This is bought for cash and sent down the river, the headmen keeping the advance for further operations.—*Engineer*, 1889, 117.

NEW LEAD MINES IN RUSSIA.

Very extensive lead deposits have been recently discovered in the upper basin of the river Kubina and its affluents. The most important find is at Katherinskoe, but the others are also valuable. The use of lead has been probably at least doubled in Russia during the last five or six years, and the increased demand led to explorations for further supplies being conducted, under Government patronage, in the Kirghiz steppes and elsewhere. Those conducted in Kirghiz yielded but scanty results; but the efforts of the promoters were very successful in the Kubina basin, and works are there to be started immediately.—*Ironmonger*.

A NEW TEXTILE.

According to the French *Revue des Colonies*, a new textile plant which is called "kamall" by the natives, has been discovered on the shores of the Caspian; and M. O. Blakenbourg, an engineer and chemist, has obtained from it a soft, elastic, and silky material, which gives a very tough thread, and can be chemically bleached without losing its strength. It can also be dyed. It is specially adapted for sacks, tarpaulins, ropes, &c., and it is stated that its specific weight is much less than that of hemp, whilst its tensile strength is greater.

DRAWBACK ON SPIRITUOUS PREPARATIONS.

The following are the settled terms of the new General Order, dated March 1889, relating to the drawback on spirituous medicinal preparations. This Order amends that given in this Journal, December No., 1888, p. 875.

The Board having had under further consideration the conditions prescribed by the General Order of the 26th November last, under which certain tinctures, liniments, and medicinal spirits (hereinafter referred to as tinctures) may be exported, and repayment allowed of the duty on the spirits estimated to be lost in the manufacture of such tinctures, &c.:—

Ordered:

That the tinctures be allowed to be packed in cases containing two or more complete bulk gallons instead of five as heretofore.

The size of the bottles containing the tinctures may range from a quarter of a pint to half a gallon instead of from one pint to half a gallon, as heretofore, and the bottles may contain any of the following quantities, viz.:— $\frac{1}{4}$ -pint, $\frac{1}{2}$ -pint, 1 pint, 2 pints, or 4 pints.

The Form No. 111—4 is to be revised by the addition of a column, in which the actual alcoholic strength of the tinctures is to be entered by the rectifier or compounder exporting them.

A corresponding additional column is also to be added in the officer's book for exporter's declaration of strength of spirit in terms of proof.

One sample out of every ten, or fraction of ten kinds of tinctures prepared at each of the two initial strengths is, as a rule, to be

taken by the officer, instead of a sample of each kind as heretofore. A larger proportion of samples, may, however, be taken should the officer, in his discretion, consider it necessary. The quantity taken for a sample is in future to be one gill. In the cases of compound spirit of ammonia and of sweet spirits of nitre, samples will always be taken.

If on examination of a sample at the laboratory the strength is found to vary by not more than two degrees from that declared by the rectifier or compounder, the declaration will be regarded as correct, and drawback, &c. allowed accordingly.

If the strength found be less than that declared by more than two degrees, a deduction to the extent of the difference, and a further deduction of one degree is to be made in calculating the proof quantities of all the tinctures of the same initial strength in the consignment, but if the difference amounts to five degrees, double that difference is to be deducted from the laboratory strength in calculating the proof quantity.

In future medicinal tinctures of every sort may be exported in cases of a minimum size of two gallons, under the provisions of the General Order of 26th November 1888, as now amended, but tinctures not included in the list appended to that Order, or in the supplementary list issued herewith, will be entitled to drawback and the allowance of 4d. per gallon only, but not to the special allowance for waste granted in respect to tinctures included in those lists.

	1887.	1888.
Imports	61,114	73,768
Exports	62,606	47,133

BOARD OF TRADE RETURNS.

The Trade and Navigation Returns for February are of a more mixed kind than those of the preceding month. Imports show an increase of 92 per cent., which is as much as they did in January, but exports have decreased 13 per cent. It would be foolish to lay any stress on these figures yet, especially as the imports of raw materials for textile industries continue as heavy as those of food. A mere accident of weather often affects the totals on both sides in the winter months, and the fact that last year gave February the extra working day of leap year would be quite enough to account for the smaller exports. Subjoined are the usual summary tables for the month:—

Imports.

Compared with February 1888.

	Total.	Increase.	Decrease.

THE SALT UNION.

The Salt Union have issued their price list for March. Since the Union recently took over various Cheshire saltfields they have raised the price of common salt from 7s. 6d. to 13s. 6d., butter salt 7s. 6d. to 15s. 6d., Calcutta salt from 8s. 6d. to 16s. 6d., and banded squares for domestic use from 13s. 6d. to 35s. per ton.—*Manchester Evening News*, 8.3.89.

ACID PRODUCTION IN FRANCE.

For the past two years the quantity of sulphuric acid produced has largely increased. Although the exportation in 1888 was 6,000,000 kilos. (6,000 tons) less than in 1887, it was 5,000,000 kilos. more than in 1886. Much of the chemical is used for the manufacture of superphosphates, also quantities of acid at 66° have been required for making melinite. Pyrites are largely employed. Southern manufacturers preferring the Spanish mineral, and Northern the mineral pyrites, as well as the Swedish, which contain no arsenic. The importation of pyrites was, in 1886, 22,000 tons; in 1887, 24,000; and in 1888, 30,000; while the exportation for the same periods was 23,500, 19,500, and 21,500 tons. As to sulphur, 192,000 tons were imported during the three years now considered. Muratic acid has experienced similar changes, the production and importation having increased in 1888, while the exportation was about a thousand tons less than the year preceding.—*Chemist and Druggist*.

THE RAILWAY AND CANAL TRAFFIC ACT.

BOARD OF TRADE NOTICE.

The Board of Trade have extended the period within which objections may be lodged against the classifications of merchandise traffic and schedules of maximum rates and charges submitted by the various railway companies, under the provisions of the Railway and Canal Traffic Act, 1888. The period, as originally fixed for lodging objections, would, in the case of the majority of the railway companies, have expired on or about April 9. It having been strongly represented that the period allowed was insufficient, it has now been extended to the 3rd of June next, before which date all objections against the proposed classifications of merchandise traffic and schedules of maximum rates and charges should be transmitted to the Board of Trade.—*Standard*, 22.3.89.

A SUGGESTED CLASSIFICATION OF CHEMICAL MERCHANDISE,
AS APPROVED BY THE CHEMICAL COMMITTEE OF THE
MANCHESTER CHAMBER OF COMMERCE.*

The following is the classification of chemical merchandise suggested by the Committee:—

CLASS A.

In owners' waggons, and at owners' risk. Not sheeted, loaded, and unloaded by owners.

(a) Minerals and all non-combustible solid chemicals, and raw materials used in the chemical and allied industries, in bulk, and in quantities of not less than four tons.

(b) Liquids, when sent in vendors' or purchasers' tank-waggons in quantities of not less than five tons.

(a) Such as for example:—

Acetate of lead.	Bichromates.
Acetate of lime.	Bisulphite of soda.
Acetate of soda.	Blacklead.
Alabaster.	Blanc fixe.
Alum.	Bleaching powder.
Alum cake.	Blue, powder and stone.
Alum waste.	Box ore.
Alumino-ferrie cake.	Bone-ash.
Alumino-silicic cake.	Bones.
Antimony ore.	Bone waste.
Antimony ore waste.	Boric acid.
Antimony regulus.	Borax.
Arsenate of soda.	Bronze powder.
Arsenic.	Cake for cattle.
Asbestos.	Carbonate of ammonia.
Barytes.	Carbonate of lime.
Bicarbonate of soda.	Carbonate of potash.

* Note.—This classification is also under consideration by the Chemical Committee of the London Chamber of Commerce.

Carbonate of soda.
Calamine.
Caustic potash.
Caustic soda.
Cement.
Cement stone.
Chalk.
Chalk lime.
Charcoal.
China clay.
China stone.
Chlorate of potash.
Chloride of calcium.
Chloride of zinc.
Chromate ore.
Cinnabar ore.
Citric acid.
Clay.
Coal and cannel.
Coal cinders.
Coal fuel (patent fuel).
Cobalt ore.
Coke.
Colours and pigments (dry).
Coppers.
Copper ore.
Copper precipitate.
Copper regulus.
Cuprolites.
Cryolite.
Culm.
Disinfecting powder.
Dross (metal).
Dye liquor refuse.
Earth (red).
Emery.
Emery dust.
Emery stone.
Farinaceous substances (such as flour, starch, farina, sago, &c.).
Fuller's earth.
Gauze.
Gas carbon.
Gas lime.
Gas purifying refuse.
Guano.
Gypsum.
Infusorial earth.
Iron ore.
Iron ore refuse for and from gas purifying.
Iron pyrites.
Iron salts, in crystal or powder.
Kainit.
Lead ashes.
Lead ore.
Lias lime.
Lime.
Limestone.
Litharge.
Magnesia.
Manganese ore.
Manure of all kinds.
Mill scale.
Mineral white.
Muriate of ammonia.
Muriate of manganese.
Muriate of potash.
Nickel ore.
Nightsoil.

Nitrate of baryta.
Nitrate of copper.
Nitrate of lead.
Nitrate of soda.
Nitro cake.
Ochre.
Oxalic acid.
Oxide of iron.
Peat.
Pipeclay.
Pitch (coal-tar).
Plaster.
Plaster stone.
Plumbago.
Plumbago ore.
Pumice-stone.
Putty.
Pyrites.
Red lead.
Red and purple ore.
Rock crystal.
Rock phosphite.
Rock salt.
Rotten stone.
Sal-ammoniac.
Salt.
Salt-cake.
Salt-petre.
Scrap tin.
Scrap zinc.
Silicate of soda.
Silicate cotton.
Silver ore.
Silver precipitate.
Skimmings flux.
Slack.
Slag or scoria.
Slag wool.
Soapstone.
Soda.
Soda-ash.
Soda crystals.
Spar.
Sulphur.
Sulphur ore.
Stannate of potash.
Stannate of soda.
Stone blue.
Sugar of lead.
Sulphate of alumina.
Sulphate of ammonia.
Sulphate of copper.
Sulphate of iron.
Sulphate of lime.
Sulphate of potash.
Sulphate of soda.
Talc.
Tap or mill cinder.
Tartaric acid.
Terra alba.
Tin crystals.
Tin ore.
Ultramarine (*see* Dry colours).
Umber (*see* Dry colours).
Verdigris.
Whiting or whitening.
White lead (*see* Dry colours).
Zinc ashes.
Zinc ore.
Zinc white (*see* Dry colours).
&c., &c.

CLASS 1.

In companies' waggons and at companies' risk. Sheeted.

- (a) All solid merchandise from Class A, when in smaller quantities than two tons but not less than five cwts.
- (b) All solid combustible chemical merchandise not giving off any inflammable vapours under or at 170° F., securely packed in bags, casks, drums, boxes, or boxes.
- (c) Also all non-combustible liquid and semi-liquid chemical products, securely packed in wooden casks or in iron or steel drums. Goods belonging to Class 4 excepted.

(b) Such as for example:—

Albumen.	Hoofs and horn waste.
Alkanet root.	Hoofs, horns, and horn tips.
Aloes.	Horn piths or sloughs.
Amber.	Ivory.
Angelica root.	Ivory black.
Anatto.	Ivory waste.
Anthracene.	Juniper berries.
Argol.	Lamphack.
Asphaltum.	Myrobala.
Bark.	Oleic acid.
Beeswax.	Orchella weed.
Burns and corks.	Paraffin scale.
Carbolic acid (solid).	Paraffin wax.
Cochineal.	Petroleum grease.
Coal-tar colours.	Rabbit fur.
Dextrine.	Rosin.
Dry divi.	Sealing wax.
Dye-woods.	Seaweed.
Fat (raw).	Sheep dipping powder.
Fenugreek seeds.	Shellac.
Feshmes and glue pieces.	Soup.
Gallnuts.	Stearine.
Gambier.	Sugar.
Gelatin.	Sumac.
Glucose.	Tallow.
Glue.	Turneric.
Gums.	Valonia.
Gutta-percha.	Vaseline.
Hair.	Vegetable ivory.
Hempseed.	Vegetable wax.
Hides and hide cuttings.	Whalebone.
Hops.	Weald.
India-rubber.	Yellow Persian berries.
Indigo.	&c., &c.
Isinglass.	

(c) Such as for example:—

Acetic acid.	Lime water.
Alizarine.	Liquid ammonia.
Alum water.	Logwood liquor.
Bisulphite of lime.	Madder.
Carbolic acid (liquid).	Mordanting liquors.
Colours (liquid or in paste).	Sheepwash.
Distilled water.	Sumac liquor.
Dye extracts.	Syrup.
Extracts of tan.	Tin liquor.
Ind.	Tobacco juice.
Iron liquors (such as nitrate of iron).	Treacle.
Lemon juice.	Vinegar.
Lime juice.	Washing fluid.
	&c., &c.

CLASS 2.

In companies' waggons and at companies' risk. Sheeted.

- (a) Combustible liquids, not giving off any inflammable vapour at less than 150° F., packed in wooden casks or in iron or steel drums.
- (b) All returned empty packages, such as crates, bags, sacks, boxes, casks, earboys, drums, hampers, &c.
- (c) Also all miscellaneous collections and consignments of drugs and chemicals, not containing any corrosive or inflammable substances, when packed together in hampers.

(a) Such as for example:—

Vegetable oils.	Glycerin.
Mineral lubricating oils.	Carbolic acid (liquid).
Blacking.	&c., &c.

CLASS 3.

- (a) All non-combustible and non-corrosive chemical liquids, in glass carboys, cans, tins, and jars, and in bottles securely packed in cases, at companies' risk.
- (b) Also all merchandise from Class 5, when in consignments of not less than two tons, and at owners' risk, subject to well-defined regulations.

CLASS B.

In companies' waggons and at companies' risk. Sheeted if and when necessary.

- (a) All merchandise from Class A when securely packed in bags, casks, or drums, in consignments of not less than four tons.
- (b) Also all merchandise from Classes 1, 2, and 3a, when securely packed, in consignments of not less than four tons and carried at owners' risk.

CLASS C.

In companies' waggons and at companies' risk. Sheeted if and when necessary.

- (a) All merchandise from Class A, in consignments of less than four tons, but not less than two tons.
- (b) All merchandise from Classes 1, 2, and 3a, when securely packed, in consignments of less than four tons, but not less than two tons, and carried at owners' risk.
- (c) Also all merchandise from Class 4, when securely packed according to well-defined regulations, in not less than truck loads, and carried at owners' risk.

Anthracene oil.
Coal-tar.
Coal-tar creosote.
Coke-oven oils.
Crude ammoniacal water (crude gas liquor).
Concentrated gas water.

Crude naphtha.
Gas-tar.
Light oils.
Muriatic acid.
Oil of vitriol.
&c., &c.

CLASS 4.

All merchandise in this class to be subject to well-defined regulations as to packages and procedure.

In companies' waggons, at owners' risk.

Mineral acids and other corrosive chemicals not giving off any inflammable vapours, in glass carboys or other approved packages, or in bottles securely packed in cases, according to well-defined regulations. Such as for example:—

Arsenic acid.	Nitric acid.
Aquaforis.	Oil of vitriol.
Dipping acid.	Phosphoric acid.
Fluoric acid.	Sulphuric acid.
Muriatic acid.	Ac., &c.

CLASS 5.

All merchandise in this class to be subject to well-defined regulations as to packages and procedure.

In companies' waggons at owners' risk.

(a) All volatile inflammable liquids giving off inflammable vapours at temperatures between 73° F. and 150° F., packed in wooden casks or in iron or steel drums.

(b) All volatile inflammable liquids giving off inflammable vapours under a temperature of 73° F., but not commencing to boil below 160° F., packed in wooden casks or in iron or steel drums.

(c) Also all volatile inflammable liquids boiling below a temperature of 160° F., in iron or steel drums only.

(a) Such as for example:—

Solvent naphtha. | Tolnol.

Ac., &c.

b) Such as for example:—

Benzol. | Crude naphtha.

Benzoline. | Ac., &c.

(c) Such as for example:—

Gasoline. | Bisulphide of carbon.

Ether. | Ac., &c.

Criticisms or suggestions for amendment should be addressed either to Mr. George E. Davis, 5 John Dalton Street, Manchester (Honorary Secretary of the Chemical Committee of the Manchester Chamber of Commerce), or to Mr. Kenrick B. Murray, Botolph House, Eastcheap, E.C., Secretary of the London Chamber of Commerce.

THE NEW PROPOSED RAILWAY RATES.

In order to facilitate comparison of the new proposed railway rates with those at present in force for specific substances, and also with the classification approved by the Chemical Committee of the Manchester Chamber of Commerce, we have calculated the cost of carriage of merchandise of each class from the Schedule of Maximum Rates deposited with the Board of Trade by five of the leading companies.

The station and service terminals have been reckoned as comprising one large town and an "other place," so that if both terminals were large towns the charges would be slightly more than are indicated in the tables.

CLASS A. SLACK. INCLUDING TERMINAL CHARGES.

	10	20	30	40	50	100	200
	Miles.	Miles.	Miles.	Miles.	Miles.	Miles.	Miles.
L. & N. W. Ry. Co.,	s. d. 1 10½	s. d. 2 7½	s. d. 3 4½	s. d. 4 1	s. d. 4 9½	s. d. 7 11½	s. d. 14 2½
L. & Y. Ry. Co.,	s. d. 1 10½	s. d. 2 7½	s. d. 3 4½	s. d. 4 1	s. d. 4 9½	s. d. 7 11½	s. d. 14 2½

There is no "Service Terminal" proposed for this class. The "Station Terminal" at each end is named at s.d. per ton in large towns as defined, and 6d. per ton at any other station. The large towns on the L. & N. W. Ry. system are London, Liverpool, Bootle, Manchester, Salford, and Birmingham. The large towns on the L. & Y. Ry. system are Liverpool, Bootle, Manchester, and Salford.

SPECIMEN DIAGRAM OF THE PROPOSED OLD AND NEW MAXIMUM RATES.

EXISTING MAXIMUM RATES in force on the NORTH-EASTERN RAILWAY ACT, 1854—at *pence per ton per mile*, covering Road Toll, use of Waggon, Locomotive, and every expense incidental to such conveyance; the proposed Rates here given are inclusive of the same.

CLASSIFICATION IN SPECIAL ACT.

At Pence per Ton per Mile.	Manure.	Lime, Lime- stone.	Iron- stone, &c.	Lead Ore.	Hides, Sugar.	Dye- Woods.	Earthen- ware.	Metals, except Iron.	Coal and Coke.	Drugs and Manu- factured Goods.
	<i>d.</i>	<i>d.</i>	<i>d.</i>	<i>d.</i>	<i>d.</i>	<i>d.</i>	<i>d.</i>	<i>d.</i>	<i>d.</i>	<i>d.</i>
Existing rates for goods carried under 20 miles.....	1'50	1'50	2'0	2'0	2'75	2'75	2'75	2'75	1'75	3'50
Existing rates for goods carried 20 miles and over, for whole distance	1'0	1'0	1'50	1'50	2'0	2'0	2'0	2'0	1'50	3'0
Existing rates for goods carried above 30 miles	1'0	..
Existing rates for goods carried under 40 miles, and intended for shipment.....	1'50	..
Proposed new rates for goods carried first 10 miles.....	6'10	3'80	3'20	6'10	10'70	9'0	12'40	..	3'20	14'10
Proposed new rates for goods carried next 20 miles.....	3'28	2'10	1'73	3'28	5'50	4'83	6'30	..	1'73	7'
Proposed new rates for goods carried remainder of distance—say 10 miles—so as to make 40 in all.....	2'83	1'82	1'48	2'83	4'86	4'0	5'47	..	1'48	6'8

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

2806. A. Waldbauer, London. Centrifugal apparatus for continuously washing, dyeing, drying, impregnating, and otherwise treating various materials and fabrics. February 18.

2837. Clement, Baron of Bechtolsheim, London. Centrifugal separators. February 18.

3016. Sir B. Samuelson, Bart.—From G. Maffei, Italy. Separating liquids of two different densities. February 20.

3065. W. S. Squire. Machinery for the separation of solid matters from liquids, and for washing out and exhausting the solid matters so separated. February 21.

3208. P. Pierrard. A method and apparatus for determining the density of fibrous, porous, or pulverulent substances, and application thereof in valuing wool and other textile materials. February 22.

3306. S. P. Thompson. Improvements in polarimeters and saccharimeters. February 25.

3311. D. C. Mackenzie. Apparatus for evaporating, condensing, distilling, drying, and heating solid and liquid matter, for chemical, pharmaceutical, and other purposes. 25 February.

3317. W. Simms and E. Houghton. Gas furnaces. February 25.

3644. J. J. Meldrum. Apparatus for distributing air or gases to liquids. Complete Specification. March 1.

3705. R. Hollingdrake. Chilled fire-bars, designed for burning smoke for furnaces of all descriptions. March 2.

3736. M. J. E. Vassel. Apparatus for filtering liquids, or for preparing extracts from substances. March 2.

3753. O. M. Row. Apparatus for condensing steam or other vapours, applicable also for heating or cooling fluids. March 4.

3778. C. W. Guy. Tubes or hollow vessels for cooling, heating, and evaporating liquids. March 4.

3779. C. W. Guy. Tubes or hollow vessels for cooling, heating, and evaporating liquids. March 4.

3963. W. Prickarts. Improvements in and relating to reverberatory and roasting furnaces, or the like. Complete Specification. March 6.

4164. C. W. Guy. Improvements in evaporating apparatus. March 9.

4228. P. de Mol and A. Gerken. Filters. March 11.

4340. D. Halpin and P. W. Willans. Means and apparatus for condensing steam. March 12.

4354. E. B. Parnell. Calcining furnaces. March 12.

4612. J. Hibbert and B. T. Haworth. Improvements in pump valves and other valves, particularly applicable to valves subjected to acid or chemical action. March 16.

4620. J. L. Fletcher. Apparatus or means for separating solid from liquid matter. March 16.

COMPLETE SPECIFICATIONS ACCEPTED.*

1888.

4689. A. Rathbone. Apparatus for cooling, heating, and condensing fluids. February 27.

4851. J. K. Kilbourn. Compression pumps for gaseous fluids. March 6.

5118. W. Schmidt. Method and apparatus for cooling and condensing vapours. February 27.

5812. R. Shackleton. Method and apparatus for superheating steam. February 27.

5829. W. Fairclough. Means for automatically removing scum, impurities, and deposits from boilers, separators, filters, &c. February 27.

6047. O. Murray.—From P. P. Aries. Apparatus for heating liquids, or maintaining them at a certain temperature. February 27.

6124. W. Smith. Machine for agitating or mixing solid and liquid substances. March 13.

6282. O. E. Borend. Means for filtering liquids. March 6.

6874. F. D. Delf. Apparatus for use as retort or filter stands. March 20.

7000. I. S. McDougall, J. T. McDougall, R. K. Hartley, and T. Nuxden. Apparatus for making bisulphites, &c. for the treatment of wood pulp and other fibrous materials. March 20.

1889.

2030. W. Sayer. Apparatus for forcing, exhausting, or pumping air, gases, liquids, &c. March 20.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

2914. J. D. Averell. Apparatus and process for manufacturing gas. Complete Specification. February 19.

2964. H. Bate. A new method of, and appliance for intensifying the light of gas, oil, and other illuminating media. February 19.

3008. A. McDougall. Improvements in the continuous firing of retorts for gas making, for bituminous, mineral, shale, or peat distillation, and other like purposes. February 21.

3137. W. C. Owston. Improvements in the process of and apparatus for manufacturing water gas. February 21.

3201. J. Sawyer. Improvements in fire-lighters. February 22.

3219. J. Jørgensen. An improvement in the manufacture of fire-lighters. February 22.

3237. R. A. Melsom. Producing heating gas by means of a hollow metal ball and pottery plate, entitled a "perforated atmospheric gas radiating sphere and absorbent amalgam plate." February 23.

3391. G. R. Hislop. Improvements in apparatus for charging gas producers and gas or shale-oil retort furnaces with hot residual coke. February 25.

3483. A. C. Jeffrey. Improvements in the method of preparing blocks from coal for fuel and other purposes, and for utilising the waste and dross of shale, coal and coke. February 27.

3498. W. R. Hutton. Improvements in making briquettes as a fuel for household and other purposes. February 27.

3536. J. Chammon. Improvements in fire-lighters. March 6.

3982. C. Moldenhauer and W. Leybold. Improvements in the mechanical revivification of gas purifying masses. March 7.

3984. J. O. O'Brien.—From W. Underwood. Improvements in the manufacture of blocks of fuel from granulated or pulverised coal. March 7.

4040. E. L. Stacey. An improved fire-lighter, and machinery for manufacturing the same. March 7.

4124. J. Maclear. Improved means of increasing the luminousness of ignited gas. March 8.

4168. W. Parbly. An improved instrument for clearing gas-retort ascension pipes. March 9.

4170. J. W. Spencer. Improvements in gas generators. March 9.

4288. A. Besson. Improvements in the manufacture of fuel. March 12.

4339. F. W. Harbord. Improvements in the manufacture and application of water gas for metallurgical and other purposes. March 14.

4544. F. Siemens. Improvements in regenerative gas furnaces and producers. March 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

3907. A. Brin. Apparatus for extraction of oxygen and nitrogen from atmospheric air. March 20.

4372. W. Foulis and A. J. Liversedge. Manufacture of gas, and apparatus therefor. March 6.

6451. E. Brook. Gas producers. March 6.

6514. A. Wilson. Gas producers. March 13.

6663. C. H. Mowll. Composition of artificial or block fuel. March 13.

7219. H. Williams. Artificial fuel. March 20.

7931. S. Chandler, sen., S. Chandler, jun., and J. Chandler. Washing and scrubbing gas, and apparatus therefor. March 6.

14585. W. M. Johnson and J. Jørgensen.—From Trafaradlingsaktieselskab Victoria Nykoping. An improved fire-lighter. March 6.

17444. G. R. Blake. A fire-lighter. March 6.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

APPLICATIONS.

3068. A. M. McDougall. See Class II.

4397. W. Young and G. T. Beilby. Improvements in the distillation of mineral oils, and in the apparatus employed therefor. March 16.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

2941. T. R. Shillito.—From J. R. Geigy, Switzerland. Production of a new violet dye or colouring matter. February 19.

3048. I. Levinstein. Improvements in the manufacture of red colouring matters suitable for dyeing and printing. February 20.

3333. T. R. Shillito. From J. R. Geigy and Co., Switzerland. Production of triphenylmethane colours dyeing with the aid of mordants. February 25.

3441. C. Dreyfus. The manufacture or production of a colouring matter or dye-stuff from phenolphthalein. February 26.

3529. B. Wilcox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture or production of indulines or induline-like dye-stuffs. February 27.

3628. A. Bang.—From Messrs. Dahl and Co., Prussia. New dye-stuffs, and the production of the same. March 1.

3642. T. Holliday and E. M. Mundviller. Improvements in the manufacture or production of bisulpho acids of beta-naphthol. March 1.

4404. S. Meyer. An improved manufacture of para-dioxybenzol in yellow stable crystals. Complete Specification. March 13.

4539. E. Eisenmann and A. Arche. Improvements in the manufacture of picric acid. March 15.

4555. H. H. Leigh.—From R. G. Williams. Improvements in colouring matters. March 15.

COMPLETE SPECIFICATION ACCEPTED.

1888.

5909. C. D. Abel.—From The Actien Gesellschaft fur Anilin Fabrikation. Manufacture of blue colouring matters. March 6.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

3023. G. F. Priestley. A new or improved machine for dressing silk waste. February 20.

3164. S. Cooper and T. Cooper. Improvements in apparatus to be employed in the manufacture of "wool wool." February 22.

3208. P. Pierrard. See Class I.

4447. G. W. Robertson, D. Black, and J. McGlashan. Improvements in the treatment of vegetable fibrous material to obtain fibre therefrom, and in apparatus therefor. March 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

7024. E. H. Hargraves. Finishing cotton goods and other fabrics. March 6.

13551. D. Nicoll. Manufacture and application of waterproof fabrics. February 27.

1889.

1172. W. Mather. Apparatus for treating textile materials with liquids, gases, or vapours. March 13.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

2806. A. Wuldbauer. *See* Class I.
 2984. T. Incham. Improvements in dyeing mixed woven fabrics. February 20.
 3105. E. Bentz, C. Edmeston, A. Edmeston, and E. Grether. Improvements in bleaching, scouring, or dyeing, or otherwise treating textile fabrics and warps or yarns, and in machinery and arrangements for the purpose. February 21.
 3257. S. Spencer and R. Holt. Improvements in apparatus for sizing, bleaching, soaping and dyeing warps. February 23.
 3291. J. Imray.—From La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, France. An improvement in indigo-dyeing. February 23.
 3312. T. Holliday. Improvements in dyeing cotton or other vegetable fibre. February 25.
 3313. T. Holliday. Improvements in dyeing cotton or other fibres black with aniline. February 25.
 3637. J. Ballantyne and G. Lamb. Improvements in apparatus for washing, scouring, bleaching, dyeing, and drying wool or other fibrous materials and yarns. March 1.
 3639. H. W. Brown. Improvements in apparatus for dyeing yarns. March 1.
 3744. S. S. Boyce and G. E. Armstrong. Improvements in apparatus for washing, dyeing, bleaching, and otherwise treating fibrous materials and piece goods. March 2.
 3934. B. Willeox.—From The Farbenfabriken vormals F. Bayer & Co., Germany. Improvements in or connected with the dyeing and printing of animal and vegetable fibres. March 6.
 3993. E. Barlow. An improved indigo-dyeing machine. March 7.
 4322. J. Gamgee. Improvements in chambers for bleaching, drying, or disinfecting clothes or other goods. March 12.
 4368. T. Holliday. Improvements in the method of production of fabrics dyed black, composed partly of animal and partly of vegetable fibres. March 13.
 4514. A. T. Clay. A new or improved machine for blowing or steaming, boiling, cooling, scouring, and dyeing woven fabrics. March 15.
 4602. H. A. Seegall. *See* Class XIII.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

6029. H. Gross, London. Process for dyeing cotton. March 13.
 18,517. H. F. Lippett. Hollow perforated tubes for dyeing, bleaching, or otherwise treating yarn in cops. February 27.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

3071. J. S. MacArthur. Improvements in obtaining cyanides from residuary liquors formed in chemical processes. February 21.
 3072. J. S. MacArthur. Improvements in obtaining cyanides from residuary liquors formed in chemical processes. February 21.
 3338. A. Collingridge.—From V. Cornet and A. Jones, France. Improvements in the manufacture of common salt, and in the construction of appliances for effecting the same. February 23.
 3407. A. Campbell and W. Boyd. Improvements in and connected with the obtaining of chlorine and sulphate of lime. February 26.
 3757. T. B. Saunders. Improvements in the method or process of treating or utilising the spent or residual liquid formed in the process of cleaning iron or steel with hydrochloric acid. March 4.
 3792. S. Daw. A method of treating waste pickle produced in tin,terne, and black-plate manufacture. March 4.
 4037. J. B. Hannay. An improved process and apparatus for the manufacture and transport of liquid chlorine. March 7.
 4195. F. Mühlenbruch. A process for producing monocarbonate of calcium. March 9.
 4239. H. W. Deacon and F. Hurter. Improvements in the manufacture or production of hydrochloric acid, and in the treatment of bisulphate of soda produced in the said manufacture. March 11.
 4286. J. Winkill, jun. An improved construction of kiln for burning limestone. Complete Specification. March 12.
 4316. E. Carez. Improvements in the manufacture of ammonium nitrate. March 12.
 4325. G. E. Carleton. Improved method and apparatus for the calcination of limestone. Complete Specification. March 12.
 4417. W. L. Wise.—From Messrs. Solvay and Co., Belgium. Improvements in the manufacture of anhydrous chloride of magnesium, and in the production of chlorine therefrom. March 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

5762. M. N. D'Andria. Manufacture of ammonia salts. February 27.
 6151. R. E. Chatfield. Ammonia carbonate applicable as baking-powder. February 27.
 6152. R. E. Chatfield. Manufacture of ammonia and its sesquicarbonate. February 27.
 7045. G. Borsche and F. Brunjes. Conversion of chloride of calcium into chloride of magnesium and carbonate of lime by means of oxychloride of magnesium and carbonic acid. February 27.
 14,061. H. J. Kirkman. Utilisation of waste pickle from tinning and galvanising works where hydrochloric acid is used in pickling. February 27.
 16,472. P. M. Justice.—From C. Dietzsch. *See* Class IX.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

3316. J. Gimson and C. Chalfinor. The placing of china saucers in closet ovens and kilns entitled "an improved thimble crank." February 25.
 3673. H. M. Ashley. Improvements in apparatus for manufacturing bottles and other hollow glass articles. March 1.
 3686. H. M. Ashley. Improvement in machinery for making bottles and other like hollow glass-ware. March 1: but ante dated November 10, 1888, being date of application in United States.
 3779. J. T. H. Richardson. An improvement in the process of manufacturing glass articles. March 4.
 4269. C. Wells and L. Ritchie. Improvements in the manufacture of earthenware articles. March 11.
 4264. T. Phoenix and G. Kirk. *See* Class XIX.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

1449. D. Gilles. Furnace for annealing thick plate glass by gradual cooling, and annealing by gas heat. March 6.
 3263. D. Rylands. Machinery for manufacture of bottles. March 6.
 5502. C. Wittowsky. Manufacture of mosaic work. March 6.
 5921. F. Kreysler and J. Mohr. Decoration of glass and ceramic ware. February 27.
 6028. M. Malvez. Apparatus for grinding and polishing plate glass. March 6.
 6980. G. Lazenby. Muffle kilns for bending and firing stained glass, tiles, pottery, &c. March 13.
 7309. J. T. H. Richardson. Manufacture of glass. March 20.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

2808. D. Storrar, Kirkcaldy. A new base, cement, or foundation for making floor covering or wall covering, and as a substitute for oxidised oil in making linoleum. February 18.
 2844. A. C. Ponton, B. L. Mosely, and C. Chambers, London. Improvements in the manufacture of artificial stone. Complete Specification. February 18.
 2919. C. C. Gilman. Improvements in or connected with fireproofing ceilings for buildings and other places or structures. Complete Specification. February 19.
 2921. C. C. Gilman. Improvements in or connected with the construction of fireproof floors and roofs. Complete Specification. February 19.
 2922. C. C. Gilman. Improvements in fireproofing wood or iron posts or columns for buildings and other structures. Complete Specification. February 19.
 2923. C. C. Gilman. Improvements in the construction of fireproof floors and ceilings. Complete Specification. February 19.
 2926. C. C. Gilman. Improvements in pavements or side walks. Complete Specification. February 19.

2962. P. Brannon and E. M. Brannon. Improvements in the employment of combinations of concreted and plastering materials with metal framing wire and ligneous and other fibre in application to fireproofing marine and other works. February 19.

3281. J. Swallow and J. H. Jackson. Improvements in the manufacture of bricks, tiles, and other forms. February 23.

3288. E. Prime. Improved apparatus for grinding cement and other analogous materials. Complete Specification. February 23.

3354. A. C. Ponton, B. L. Mosely, and C. Chambers. Improvements in and relating to blocks or bricks composed of silicious materials. February 25.

3355. W. Hubbard, B. L. Mosely, and J. S. Fairfax. Improvements in or relating to wall tiles or other wall linings. February 25.

3357. H. H. Leich.—From L. H. Clausen, Hamburg. Improvements in the process of manufacturing artificial stone. February 25.

3378. C. Güttler. An improved method and apparatus to form disintegrated or loose material, such as sugar, loam, clay, cement, mortar, turf, &c., into compact bodies. February 25.

3872. L. J. Cadwell. Improvements in pavements, and in blocks therefor. Complete Specification. March 5.

3873. R. Haddan.—From S. E. Haskin, United States. Improvements in and relating to the vulcanising of woods. March 5.

3979. H. Earnshaw. Improvements in means or apparatus employed for annealing or tempering bricks, paving blocks, and the like articles made from slag. March 7.

4060. T. Pense. An improved impregnating liquid for, and method of applying same to render wood in log, plank, or other form non-inflammable. March 8.

4077. E. A. Ashley. A new or improved fireproof starch or composition, applicable as a fireproof dressing for any suitable material. March 8.

4175. E. Mürjahn. A method of producing a useful material or materials from greenstone, diabase, and other varieties of hornblende. Complete Specification. March 9.

4285. G. A. Marsden. Improvements in and relating to the manufacture of ornamental and decorative tiles, bricks, and like articles. March 12.

4333. G. Batchelor. Improvements in arrangements for drying slurry by the waste heat from cement kilns. March 12.

4347. J. Homan. Improvements in fireproof structures, and in bricks for the same. March 12.

4509. W. Davidson. Improvements in and relating to kilns for drying granular substances. Complete Specification. March 15.

4611. W. H. Nightingale, W. Nightingale, and A. E. Powys. Improvements in the manufacture of cement. March 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

5881. A. McEa. Improvements in cement, in "cooling" same, and in apparatus therefor. February 27.

6261. J. C. Sellars. Improvements in cement. March 6.

6229. J. Elliott. Manufacture of roofing slabs, tiles, &c. March 6.

6944. H. H. Lake.—From A. Van Berkel. Manufacture of plates, slabs, or blocks for building purposes. March 13.

16,472. P. M. Justice.—From C. Dietzsch. Furnace for production of carbonic acid gas and burning of calcareous material. March 6.

19,010. G. H. Sharpe and F. W. Turner. Manufacture of cement suitable as plaster and for moulding purposes. March 6.

1889.

1765. L. Brentini. Roofing tiles. March 6.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

2931. E. B. Parnell. Improvements in the treatment of ores for the recovery of metals, and in apparatus therefor. February 19.

2965. W. H. Melaney. Improvements in and relating to the manufacture of safe and armour plates. February 19.

2986. T. Middleton, jun. An improved method of and means for producing steel castings. February 29.

3098. R. H. Braddon. Improved process and apparatus for effecting the hardening of steel. Complete Specification. February 21.

3109. P. Elhs. A new or improved metallic alloy. February 21.

3149. A. J. Boulton.—From W. G. Clark. Improvements in or relating to the coating of metals. February 21.

3286. G. C. Fricke. An improved method of renewing waste pickling liquors and recovering the metals in solution, with apparatus therefor. February 23.

3486. J. E. Bennett. Improvements in the treatment of metallic chlorides for extraction of metals therefrom. February 27.

3497. E. T. Phipson. Combining plates of iron and of copper by means of a flux. February 27.

3555. T. Slater, G. E. A. Holdsworth, and W. V. Williams. Improvements in metallic alloys and refinement of metals, and fluxes used therewith. March 1.

3916. D. I. Reisz, M. Berkovits, and J. Biehler. An improved metallic alloy for syphon heads and other objects, and for tinning purposes in general, denominated nickel tin. Complete Specification. March 6.

4003. E. Lones, R. Davies, J. Davies, and B. A. Webb. Improvements in coating metal plates or sheets with tin and other metals, and apparatus therefor. March 7.

4043. T. Bell. Improved means or method of lining barrels and like vessels to resist acids used when extracting metals by chlorination or similar process from their ores. March 7.

4953. C. J. L. Leffler. Improvements in hardening hollow or tubular pieces of steel, and in apparatus therefor. March 8.

4151. J. Clegg. Improvements in metals and alloys. March 9.

4169. J. L. E. Daniel. An improved process for the manufacture of aluminium, and apparatus therefor. March 9.

4335. W. E. Everitt. A new or improved method of coating plates and sheets of iron with copper or brass, and apparatus to be employed in effecting the said coating. March 12.

4353. A. M. G. Sebillot. Improvements in copper and silver leaching processes and apparatus. March 12.

4428. N. C. Cookson. Improvements in coating iron with antimony. March 14.

4439. F. W. Harbord. See Class II.

4521. J. S. MacArthur, R. W. Forrest, and W. Forrest. Improvements in and connected with the obtaining of gold and silver from solutions containing them. March 15.

4547. A. Hodgkinson, jun. The better extraction of iron from the calcined products of various ironstone mines and shale. March 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

3547. L. Q. Brin. Method and apparatus for making aluminium bronze. March 13.

4034. H. F. Taylor and W. P. Struvé. Apparatus connected with pots for coating with metals or alloys. March 20.

4350. H. F. Taylor and W. P. Struvé. Apparatus for pulverising ores, &c. March 20.

5061. H. Müller. Safety fuzes for firing charges without danger from fire-damp. March 6.

5084. T. Twynnam. Manufacture of ingot iron and steel. February 27.

5316. S. Pearson, J. Liddon, and J. H. Pratt. Manufacture of aluminium and alloys thereof. March 13.

5386. T. Twynnam. Manufacture of ingot iron and steel, and treating the resulting slag for the production of alkalis and alkaline salts. March 20.

5717. P. F. Dillon and J. J. Doyle. Moulds for casting metals. March 6.

6104. J. Weirich. Treating auriferous and auro-argentiferous ores. February 27.

10,347. C. C. Townsend. Manufacture of malleable iron castings without annealing. March 13.

14,061. H. J. Kirkman. See Class VII.

17,333. G. M. Westman. Process and furnace for manufacture of zinc, iron, phosphorus, sodium, &c. February 27.

18,088. L. Keyling. Process and apparatus for producing pieces of iron, steel, and other metal. February 27.

18,477. G. C. Dymond.—From W. H. Appleton. Machines for rolling seamless tubing, columns, &c., from hollow ingots. February 27.

1889.

1590. W. E. Koch. Apparatus for casting steel pipes. March 20.

2068. H. M. Redemann and R. J. Tilford. Treating crude or low grade steel to produce refined or high grade steel. March 13.

2069. H. M. Redemann and R. J. Tilford. Same object as No. 2068. March 13.

2070. H. M. Redemann and R. J. Tilford. Same object as No. 2068. March 13.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

2885. R. H. C. Neville. Improvements in methods and apparatus for charging secondary batteries or electrical accumulators. February 19.
2943. S. D. Williams. Improvements in dynamo-electric machines. February 19.
2949. E. D. Cross. Improvements in galvanic batteries. Complete Specification. February 19.
3222. A. J. Boulton.—From A. K. Reinfeld. Improved process of treating plates and the like for facilitating the removal of galvanoplastic deposits contained thereon. February 22.
3502. A. G. Greenway, B. F. Babcock, and B. Radcliffe. Improvements in or connected with processes of manufacturing iron wherein the iron is subjected to an electric treatment. February 27.
3533. C. D. Abel.—From Messrs. Siemens and Halske, Germany. Improvements in the extraction of copper and zinc from their ores, as also of the precious metals contained therein, by electrolysis, and apparatus therefor. February 27.
3558. H. Kenyon. Method of obtaining aluminium continuously in an electrical furnace. February 28.
3940. G. A. Schoth. Improvements in galvanic batteries. March 6.
3971. J. J. Rathbone. Improved compound or admixture of ingredients suitable for producing electric energy. March 6.
4171. W. L. Wise.—From F. C. Glaser. Improvements in accumulators or secondary batteries. March 9.
4296. J. Kynoch. Improvements in galvanic batteries. March 12.
4559. D. G. Fitzgerald. Improvements in voltaic batteries. March 15.
4599. C. Lever. Electrolytical process and apparatus for producing bleaching powder and other materials. March 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

5191. H. Edmunds. Storage batteries. March 13.
6322. P. R. de Fauchaux d'Hunay. Galvanic batteries. March 6.
8354. M. Leclanché. Depolarisers for primary or secondary batteries. February 27.
- 16,048. W. P. Thompson.—From C. H. Thompson. Secondary batteries. March 6.

1889.

361. H. H. Lake.—From E. Thomson. Methods and apparatus for welding, forging, and working metals by the aid of electricity. March 6.
362. H. H. Lake.—From E. Thomson. Methods and apparatus for welding, shaping, and working metals by the aid of electricity. March 13.
377. H. H. Lake.—From E. Thomson. Riveting metal plates, &c. by the aid of electricity. March 6.
1401. J. T. Dyer, P. Fish, and R. C. Fish. Generating electricity. March 13.
2066. L. Paget. Manufacture of electrodes for secondary batteries. March 13.
2276. E. Guitton.—From M. Sappey. Construction and arrangement of primary batteries. March 13.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

2856. H. Ritter von Dahmen and A. Strauss-Collin, London. A new manufacture of soaps or saponaceous compounds. February 18.
5009. A. McClellan and J. W. Wareing. An improvement in the manufacture or production of soap. February 20.
4145. F. Bosshardt.—From E. de Werchin, France. Improvements in the manufacture of soap for scouring and similar operations. March 9.
4190. G. Hervieux and V. Bedard. Axle grease. Complete Specification. March 9.
4367. W. G. Reid. Improvements in the treatment of used soapy liquors. March 13.
4589. M. Williams. Improvement in the preparation of drying oils. March 16.

4406. W. P. Thompson and G. Tall. Improvements in or relating to the treating or purification of crude or semi-refined cotton-seed oil. March 16.

4651. H. C. Foulsham. An improved soap powder. March 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

5981. T. S. Saunders. An improved soap. February 27.
5985. J. Lewkowitch. Obtaining fatty acids and glycerin from fats and oils. February 27.
6669. A. J. Boulton.—From O. Korschelt. Extracting wool-oil (lanolin) mechanically. March 6.
6671. A. J. Boulton.—From O. Korschelt. Extracting wool-oil (lanolin) mechanically. March 6.
7095. W. P. Thompson.—From C. C. Parsons. Improvements in detergents in which ammonia is an ingredient. March 20.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

4179. S. Kenyon. Improvements in and in the manufacture of a preparation or substance applicable as a substitute for india-rubber, and for waterproofing or dressing cloths, sheetings, and other articles, also for other purposes. March 9.
4567. H. W. Hemingway and W. F. Thompson. Improvements in the treatment of lead for the manufacture of products applicable for use as pigments and otherwise. March 15.
4602. H. A. Seegall. Improvements in the production of chrome preparations. March 16.
4637. R. Seabrook. An improved anti-fouling compound for coating the bottoms of ships and other vessels. Complete Specification. March 16.
4650. W. A. Bes. New or improved compositions for decorative purposes. March 16.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

5878. The Belfast Paint and Colour Manufacturing Company. Perfuming paint enamels known as "Woodstock" oxydised enamels. March 6.
6012. E. F. Wailes and E. J. Dove. Compositions for coating metal structures, and apparatus for applying same. February 27.
7033. J. B. Hannay. Preservative and anti-fouling coatings for ships. March 20.
- 11,554. W. O. Wotton. Anti-fouling composition. March 13.
- 17,946. F. J. Binns and R. J. Paris. Composition for ships' bottoms, &c. March 6.

1889.

722. J. Y. Johnson.—From G. Fell. Manufacture of lead pigments. March 6.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

3964. G. Johnson and H. Clarke. Improvements in sole leather. Complete Specification. March 6.
4408. A. F. S. Grant and W. Francis. Improvements in tanning. March 13.
4415. G. Mitchell and R. W. Rutherford. An improved process for preparing skins and hides for tanning. March 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

742. L. A. Groth. Apparatus for tanning by the aid of electricity. March 20.
6491. H. Levick. Improvements in tanning. March 6.

XV.—AGRICULTURE, MANURES, Etc.

APPLICATIONS.

4450. W. Y. Hardie. See Class XVI.11.—B.
4655. T. C. Darby and G. C. Phillips. Improvements in the preparation of manure, and in apparatus to be used for this purpose. March 16.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

2960. A. Mally. Improvements in apparatus for moulding or pressing sugar into suitable forms. February 19.
3378. C. Guttler. See Class IX.
3526. A. G. Salamon. Improvements in the preparation of cane and beet sugar. February 27.
4121. F. Demmin. Improved method for cleansing or whitening sugar in the centrifugal machine, and apparatus therefor. March 8.
4444. J. Grass and O. Olme. Improvements in the manufacture of saccharine liquors for brewing and other similar purposes, and in the mode of their manufacture. March 14.

COMPLETE SPECIFICATION ACCEPTED.

1888.

6698. G. Fletcher. Sugar-cane mills. February 27.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

2953. A. Seelbach. An improvement in the manufacture of champagne and like wines. Complete Specification. February 19.
3468. B. Hoff. Improvements relating to distillation and apparatus therefor. February 26.
3574. M. P. Halsechek. An improved system of "pneumatic malting." February 28.
3598. C. E. Mumford. Improvements in tides for malt-kiln floors. Complete Specification. February 28.
3706. J. Mitchell. Improvements in filtering sediment from distilleries and in other similar filtering operations, and in the apparatus employed therefor. March 2.
3797. C. R. C. Tiebhorne, A. Darley, and M. F. Percell. The collection and the utilisation of the carbonic acid and other products given off during the process of all fermentations. March 2.
4444. J. Grass and O. Olme. See Class XVI.
4549. E. A. Barbet. Improvements in process for rectifying and distilling alcohol, and in apparatus therefor. March 15.

COMPLETE SPECIFICATION ACCEPTED.

1888.

- 13,675. J. Hemming. Pneumatic malting drums. March 13.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—CHEMISTRY OF FOODS.

2820. R. M. Houldsworth, London. A tea compound. Complete Specification. February 18.
3019. E. Sonstadt. Improvements in processes and apparatus for the preparation of an extract of tea, and in the utilisation of the by-products. February 20.
3168. C. Garnier. A new or improved process for the preservation of animal substances, and apparatus for use therewith. February 22.
3172. E. Sonstadt. Improvements in processes and apparatus for the preparation of an extract of coffee, and in the utilisation of the by-products. February 22.
3210. W. H. Pearce. An improved process for preserving fruit, &c. February 22.

3577. P. G. Oster. A new compound or article of food, applicable for preparing a beverage similar to coffee, and process for making the same. February 28.

4391. S. Marmont. A process of and means for curing or preserving all kinds of fish, flesh, and fowl, and apparatus therefor. Complete Specification. March 13.

B.—SANITARY CHEMISTRY.

4058. H. Guthrie. Improvements in treating sewage, and in the construction and arrangement of means therefor. Complete Specification. March 8.
4411. J. B. Paddon. Improvements in the method of and apparatus for destroying town and other refuse material. March 13.
4450. W. Y. Hardie. Improvements in the method of and means for destroying or otherwise treating towns' refuse and sewage sludge, and purifying the fumes and gaseous vapours emitted therefrom, and preparing and utilising the by-products and residuals for commercial and agricultural purposes. March 14.
4620. J. L. Fletcher. See Class I.

C.—DISINFECTANTS.

2858. W. H. Daniels. An improved antiseptic compound for preserving perishable articles. February 18.
3159. R. Hannan. Improvements in sanitary materials or preparations. February 22.
3470. A. M. Clark.—From E. Bean, United States. An improved insect-destroying compound, and method of preparing same. February 26.
3728. A. H. Mason.—From Messrs. Senbury and Johnson, United States. A fumigating or disinfecting candle. March 2.
4387. H. Oppenheim. Tablets for disinfecting, antiseptic, medical, bleaching, and laundry purposes. Complete Specification. March 13.

COMPLETE SPECIFICATIONS ACCEPTED.

B.—SANITARY CHEMISTRY.

7307. A. Fawcett. Apparatus for the clarification of sewage. March 20.
8371. W. Edwards. Prevention of the pollution of watercourses; purifying ordinary river waters for use; and recovery of materials used by paper-makers, dyers, and others. March 20.

C.—DISINFECTANTS.

6738. J. W. Knights and W. D. Gall. Automatic distribution of disinfecting or antiseptic fluids for deodorising the atmosphere. February 27.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

4264. T. Phoenix and G. Kirk. Improvements in the preparation of tissue transfer paper, and of printed transfers for transferring designs on to pottery ware.
4452. E. Partington. Improved apparatus for separating or disintegrating fibres in the manufacture of paper. March 14.

COMPLETE SPECIFICATION ACCEPTED.

1888.

3787. T. J. Pearce and M. W. Beardsley. Manufacture of paper having waterproof and non-conducting qualities. March 13.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATION.

3745. A. Domcier. Improvements in extracting and fixing perfumes. March 2.

COMPLETE SPECIFICATION ACCEPTED.

1888.

3094. L. Merck and E. Menck. Production of hydrargyrum compounds. February 27.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.*APPLICATION*

4324. G. C. Whitfield. An improvement in film photography. March 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1888.

7044. R. Norris. Production of collodion films on surfaces of great sensitiveness. March 6.

1889.

1461. W. J. Wilson. Photographic transparencies. March 6.

XXII.—EXPLOSIVES, MATCHES, Etc.*APPLICATIONS.*

3761. H. C. L. Helden. Improvements in electric tubes and fuzes for firing ordnance and exploding torpedoes and mines, and for like purposes. March 4.

4477. H. S. Maxim. Improvements in the manufacture of explosive compounds. March 14.

4479. A. V. Newton.—From A. Nobel. Improvements in the preparation of explosive compounds. March 14.

4539. E. Eisenmann and A. Arche. Improvements in the manufacture of picric acid. March 15.

COMPLETE SPECIFICATION ACCEPTED.

1888.

6560. A. V. Newton.—From A. Nobel. Explosive compounds. March 6.

THE JOURNAL

OF THE

Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 4.—VOL. VIII.]

APRIL 30, 1889.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2/6.]

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.

COUNCIL FOR YEAR ENDING JULY, 1889.

President: Ludwig Mond.

Vice-Presidents:

<i>Sir I. Lowthian Bell, F.R.S.</i>	<i>David Howard.</i>
<i>R. Forbes Carpenter.</i>	<i>Ivan Levinstein.</i>
<i>Prof. F. Clowes, D.Sc.</i>	<i>E. K. Muspratt.</i>
<i>Sir J. Neilson Cuthbertson.</i>	<i>Dr. W. H. Perkin, F.R.S.</i>
<i>Prof. James Dewar, F.R.S.</i>	<i>Sir H. E. Roscoe, M.P., F.R.S.</i>
<i>Dr. John Evans, F.R.S.</i>	<i>Prof. W. A. Tilden, F.R.S.</i>

Ordinary Members of Council:

<i>Alexander M. Chance.</i>	<i>F. J. Rowan.</i>
<i>James Duncan.</i>	<i>Dr. Edward Schunck, F.R.S.</i>
<i>A. E. Fletcher.</i>	<i>E. C. C. Stanford.</i>
<i>S. H. Johnson.</i>	<i>J. C. Stevenson, M.P.</i>
<i>B. E. R. Newlands.</i>	<i>T. W. Stuart.</i>
<i>B. S. Proctor.</i>	<i>Thos. Tyrer.</i>

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. Ferdinand Harter.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

<i>Arthur G. Bloxam.</i>	<i>D. A. Louis.</i>
<i>C. H. Bothamley.</i>	<i>W. Maenab.</i>
<i>E. G. Clayton.</i>	<i>G. Harris Morris, Ph.D.</i>
<i>Julius B. Cohen, Ph.D.</i>	<i>J. M. H. Munro, D.Sc.</i>
<i>C. F. Cross.</i>	<i>H. S. Pattinson, Ph.D.</i>
<i>A. R. Davis.</i>	<i>H. T. Penttermann.</i>
<i>W. W. Haldane Gee, B.Sc.</i>	<i>S. G. Rawson, B.Sc.</i>
<i>C. Napier Hake.</i>	<i>A. Ree, Ph.D.</i>
<i>S. Hamburger, Ph.D.</i>	<i>F. W. Renaut.</i>
<i>Oswald Hamilton.</i>	<i>A. J. Smith, B.Sc.</i>
<i>John Heron.</i>	<i>A. Studer, Ph.D.</i>
<i>Bertram Hunt.</i>	<i>Bertram Thomas.</i>
<i>C. C. Hutchinson.</i>	<i>Eustace Thomas.</i>
<i>D. E. Jones, B.Sc.</i>	<i>V. H. Veley, M.A.</i>
<i>W. E. Kay.</i>	<i>R. Lloyd Whiteley.</i>
	<i>A. Wingham.</i>

NOTICES.

In accordance with the provisions of Rule 18 of the Bye-laws, notice is hereby given that those Members of Council whose names are placed in italics in the annexed list, will retire from their respective offices at the forthcoming Annual General Meeting.

Sir Isaac Lowthian Bell, Bart., F.R.S., has been nominated to the office of President; and Mr. Ludwig Mond has been nominated Vice-President under Rule 11.

Dr. W. H. Perkin, F.R.S., has been nominated a Vice-President under Rule 24; Mr. James Duncan, Mr. S. H. Johnson, Dr. Hugo Müller, F.R.S., and Dr. Edward Schunck, F.R.S., have been nominated Vice-Presidents under Rule 8; and Mr. L. Archbutt, Mr. John Brock, and Mr. John Spiller have been nominated Ordinary Members of Council under Rule 17, in the place of Mr. James Duncan, Mr. S. H. Johnson, and Dr. Edward Schunck, F.R.S., nominated Vice-Presidents.

The Treasurer and Foreign Secretary have been nominated for re-election.

Members are hereby invited to nominate fit and proper persons to fill four vacancies among the Ordinary Members of Council under Rule 18. Special nomination forms for this purpose can be obtained from the General Secretary upon application.

Extract from Rule 18:—"No such nomination shall be valid, unless it be signed by at least ten members of the Society, who are not in arrear with

their subscriptions, nor unless it be received by the General Secretary, at the Society's office, at least one month before the date of the commencement of the Annual General Meeting, to the election to take place at which it refers. Nor shall any such nomination be valid if the person nominated be ineligible for election under Rules 12 or 15. No member shall sign more than one nomination form."

ANNUAL GENERAL MEETING.

Notice is hereby given that the next Annual General Meeting will be held in London on Wednesday, Thursday, and Friday the 10th, 11th, and 12th of July next. Detailed arrangements and the programme of proceedings will appear as soon as complete. Tickets of membership will be issued in time for the meeting, and will form, as heretofore, vouchers for visits to works and excursions.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Post Office Orders in payment of subscriptions should in all instances be made payable at the General Post Office, London.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

LIST OF MEMBERS ELECTED, 23rd APRIL, 1889.

d'Andria, M. N., Birch Villa, Windsor Road, Levenshulme, Manchester, manufacturing chemist.

Ball, Joseph P., 4533, Main Street, Frankford, Philadelphia, Pa., U.S.A., chemical student.

Bowing, Jno., 259, Gresham House, Old Broad Street, E.C., consulting and manufacturing chemist.

Brown, Chas. J., 12, Victoria Buildings, St. Mary's Gate, Manchester, engineer.

Brammer, Dr. Philip, Clayton Aniline Co., Clayton, Manchester, chemist.

Burger, Dr. Josua, B, Marzellenstrasse, Coln, Germany, chemist.

Cargay, Wm. G., Forest Hall, near Newcastle-on-Tyne, analytical chemist.

Chattaway, Wm., c/o A. H. Allen, 101, Leadenhall Street, E.C., analytical chemist.

Claus, Wm. H., Tonge Villa, Middleton, near Manchester, manager.

Corbould, Wm. H., Flora Bell Proprietary Silver Mining Co., Northern Territory, South Australia, assayer and analyst.

Dodd, Wm. Ralph, Dunsmure Road, Stamford Hill, N., chemical manager.

Fletcher, George, 3, East Ascent, St. Leonards-on-Sea, engineer.

Follows, F. W., Morningside, Fairfield, near Manchester, engineer.

Faukel, Lee K., 1315, Marshall Street, Philadelphia, Pa., U.S.A., instructor in chemistry.

Griffin, Roger B., 103, Milk Street, Boston, Mass., U.S.A., chemical engineer.

Harrison, Ernest M., c/o Hay-Gordon & Co, Widnes, chemical works manager.

Horton, Wm., 5, Edge Lane, Liverpool, chemical student.

Isherwood, Oswald, c/o Mather and Platt, Salford Ironworks, Manchester, chemical engineer.

Law, Arthur Ewing, c/o Jas. Muspratt & Sons, Widnes, chemist.

Meeting held Monday, April 1st, 1889.

MR. DAVID HOWARD IN THE CHAIR.

THE ACTION OF WATER ON LEAD.

BY PERCY F. FRANKLAND, PH.D., B.SC., F.I.C.,
Professor of Chemistry in University College, Dundee.

THE action of water on lead is a matter which is fortunately of but little moment in London, and in the greater part of southern England. In the northern counties, in Scotland, and generally speaking in those districts yielding soft waters, it is, however, a matter of great importance, and one which is too frequently neglected or lost sight of in connexion with the distribution of water for domestic purposes.

In the present paper I do not propose to enter into a detailed disquisition on this subject, which abounds in conflicting literature, but rather to record some of my recent practical experiences in connexion with the corrosion of leaden service pipes, and on the methods which are available for the prevention of the same.

Some time ago my attention was called to the occurrence of numerous cases of lead poisoning in a Lancashire town, and as the occurrence was naturally attributed to the water supply, in the first instance a careful examination of the latter had to be made.

The water supply of this town in question is derived from an upland gathering-ground, the upper half of which is mostly uncultivated moorland and very peaty, so much so that the stream issuing from it is sometimes of a dark-brown colour. The lower half of the gathering-ground is nearly all cultivated meadow and grazing land, but the water draining from it receives some additions of ochreous liquid from an old colliery working. Now, the water from the upper half of the gathering-ground is collected in one reservoir "A," and supplied to one part of the

town, whilst that from the lower half of the gathering-ground is collected in another reservoir, "B," and supplied to a different part of the town.

On being submitted to analysis these two waters were found to differ very considerably in composition. Thus:—

RESULTS OF ANALYSES in PARIS per 100,000.

	Water from Reservoir "A."	Water from Reservoir "B."
Total solids.....	7.80	13.40
Organic carbon.....	.158	.248
" nitrogen.....	.028	.039
Ammonia.....	.002	.004
Nitrogen as nitrates and nitrites.	0	.065
Hardness, temporary.....	0	0
" permanent.....	3.5	7.1
" total.....	3.5	7.1
Chlorine.....	1.1	1.1

Not only did these waters exhibit this difference in composition, but they diverged widely in their behaviour towards lead. Thus the harder water "B" (which had received the coal mine drainage referred to above), had practically no action on either bright or tarnished lead, whilst the softer water "A," after remaining 12 hours in contact with a small piece of bright lead, contained 1.0 part of lead in solution, and, after being similarly in contact with tarnished lead, as much as 1.2 part of lead per 100,000.

This water was, therefore, at once recognisable as one of those peculiarly troublesome ones which act both on new and old lead.

This difference in the activity of the two waters was further found to coincide with the observed fact that no cases of lead poisoning had occurred in the district supplied from the reservoir "B."

It now became necessary to inquire into the available means of rendering the water "A" inactive towards lead.

Effect of Agitation with Carbonate of Lime.—On the laboratory scale I found that this activity of the water "A" could be very easily removed by shaking the water up with precipitated carbonate of lime, and then allowing the latter to subside.

The water which had been in contact with the carbonate of lime for 12–24 hours was found to have no action on either new or old lead.

In extending the investigation of the activity of this water on lead, I employed in all my further experiments pieces of leaden service piping. These pipes were in every case 2 ft. in length, closed by beating out at one extremity, whilst the other was closed with a cork, the tube being completely filled with the water under examination.

Bearing in mind that the water had shown itself more active on old lead than new, it appeared to me very essential to make all the experiments in duplicate, one set of experiments being made with new leaden pipes, and the other with old pipes of similar dimensions and *actually taken from the services of that part of the town which was supplied with the water in question.*

The further experiments were made with samples of the water from the reservoir "A" collected in the months of February, April, and June respectively. Before detailing these experiments, it will be desirable

to record the results of analyses of these several samples, as well as of a sample of colliery water which will be referred to later on:—

RESULTS OF ANALYSIS IN PARTS PER 100,000.

	Water from Reservoir "A."			Colliery Water.
	February.	April.	June.	
Total solids.....	7.40	7.62	11.68	45.92
Organic carbon.....	.141066
" nitrogen.....	.022017
Ammonia.....	.004	0
Nitrogen as nitrates and nitrites.....	.016	0
Chlorine.....	1.1	1.2	1.3	1.0
Hardness, temporary ...	0	0	2.1	17.1
" permanent....	3.9	3.3	4.6	17.7
" total.....	3.9	3.3	6.7	34.8
Silica.....	.48	.50	.82	1.46

Experiments on the action of "A" Water on new and old Lead Pipes.—The February sample of water from "A" reservoir was placed in two new pipes of $\frac{1}{2}$ in. and $\frac{3}{4}$ in. diameter respectively. From the table below it will be seen that the water taken from the larger pipe contained more lead than that taken from the smaller one, and points to the necessity of using in all comparisons of this kind tubes of exactly the same diameter.

It was also found that the proportion of lead taken up by the water did not, within certain limits, increase by longer contact; thus generally the water, after standing two days in the tube, did not contain more lead than after standing one day.

Again, the experiments showed that there was no tendency for the quantity of lead taken up to diminish with the age of the pipe; but, on the contrary, the solvent action of the water rather increased from day to day. This important point is more prominently brought out in subsequent experiments with old service pipes.

Some of this water from reservoir "A" was subjected to a sort of crude filtration through chalk on the large scale, and a sample of this filtered water was placed in a $\frac{3}{4}$ -in. new pipe, but from the results given below it will be seen that this treatment had practically left the activity of the water unchanged, the amount of lead taken up being almost exactly the same as in the case of the unfiltered water in the pipe of the same diameter:—

I.	II.	III.
Water from "A" Reservoir.	Water from "A" Reservoir.	Water from "A" Reservoir after Passage through Chalk.
New $\frac{1}{2}$ -in. Pipe.	New $\frac{3}{4}$ in. Pipe.	New $\frac{3}{4}$ -in. Pipe.
Average daily amount of lead found during 12 days' trial.		
.36	.72	.69

Action of Colliery Water on Lead.—The colliery water, the analysis of which is given above, would from its composition be naturally supposed to have no action on lead, and this anticipation was realised on actual trial.

As this colliery water was available in large quantity, it naturally suggested itself that by blending this water with that of the "A" reservoir in suitable proportions, a mixed water might be obtained, which, without being excessively hard, would have no action on lead.

Several experimental mixtures of the two waters were, therefore, prepared and submitted to trial in leaden tubes as below:—

IV. Colliery Water.	V. 10 Vols. "A " Water + 1 Vol. Colliery Water.	VI. 10 Vols. "A " Water + 1 Vol. Colliery Water.
New $\frac{1}{2}$ -in. Pipe.	New $\frac{1}{2}$ in. Pipe.	Old $\frac{1}{2}$ -in. Pipe.
Average daily amount of lead found during 12 days' trial.		
0	.25	1.11
VII. 5 Vols. "A " Water + 1 Vol. Colliery Water.		VIII. 5 Vols. "A " Water + 1 Vol. Colliery Water.
New $\frac{1}{2}$ -in. Pipe.		Old $\frac{1}{2}$ -in. Pipe.
Average daily amount of lead found during 16 days' trial.		
.51		.98
IX. 2 Vols. "A " Water + 1 Vol. Colliery Water.		X. 2 Vols. "A " Water + 1 Vol. Colliery Water.
New $\frac{1}{2}$ -in. Pipe.		Old $\frac{1}{2}$ -in. Pipe.
Average daily amount of lead found during 12 days' trial.		
.39		.88
XI. 1 Vol. "A " Water + 1 Vol. Colliery Water.		XII. 1 Vol. "A " Water + 1 Vol. Colliery Water.
New $\frac{1}{2}$ -in. Pipe.		Old $\frac{1}{2}$ -in. Pipe.
Average daily amount of lead found during 16 days' trial.		
.69		.61
The tube was then filled with London (Thames) water, and after two days it gave .05 Pb.		The tube was then filled with London (Thames) water, and after two days it gave .70 Pb.

Thus, only when the two waters were mixed in equal proportions was the activity of the "A" water counteracted, the proportion of lead taken up being then practically the same as when London water (which is well known to be inactive) is placed in the same tubes.

Indeed, from the analyses of the two waters (the "A" water and colliery water) given above it will be seen that a mixture of the two in equal volumes has a composition very closely approximating to that of ordinary London water.

A remarkable point which is brought out in these experiments on the mixtures of the two waters is that waters containing considerable proportions of

temporary hardness may yet be by no means inactive towards lead.

A few years ago Messrs. Crookes, Odling, and Tidy referred the activity of water towards lead to a deficiency in silica; and although there are many facts which are in harmony with this theory, it will be seen that in the present instance some of the active mixtures contained more silica than the proportion (·5 grain SiO_2 per gallon or ·7 part per 100,000) which in the opinion of these investigators prevents the activity of water on lead. Thus—

Mixture.	Parts per 100,000.	
	Temporary Hardness.	SiO_2 .
"A" water (February sample).	0	·48
Colliery water	17·1	1·46
I. 10 Vols. "A" + 1 Vol. colliery water.....	1·6	·57
II. 5 Vols. "A" + 1 Vol. colliery water.....	2·8	·64
III. 2 Vols. "A" + 1 Vol. colliery water.....	5·7	·81
IV. 1 Vol. "A" + 1 Vol. colliery water.....	8·6	·97

Thus if ·7 part of SiO_2 per 100,000 confers inactivity towards lead on a water, then the mixture No. III. should have no action, whilst from the above tables it will be seen that its activity was still very marked.

The Prevention of Activity by Carbonate of Soda.—Thinking that the activity of the "A" water might possibly be counteracted by the use of an alkali, experiments were made on the effect of adding small proportions of carbonate of soda. The proportions employed were 10 and 5 parts of Na_2CO_3 per 100,000 respectively. The following results were obtained:—

XIII.	XIV.
"A" Water + 10 Parts Na_2CO_3 ½-in. New Pipe, which had been previously used for Experiments in Table I.	"A" Water + 5 Parts Na_2CO_3 per 100,000. Same Pipe as in XIII.
Average daily amount of lead found during 8 days' trial.	
0	0

The "A" water with 5 parts Na_2CO_3 was also tested over the same period of 15 days with a ¾-in. new pipe. The average amount of lead found was only ·03 part, and the maximum, which occurred on the first day, only ·05 part Pb per 100,000.

Thus, even 5 parts of carbonate was sufficient to counteract the activity of this water. A sample from the same source, however, collected in April, when the water was more peaty in character, although containing the same proportion of silica, was considerably more active towards lead, and the activity did not in this case yield to an addition of 5 parts of carbonate of soda.

I have tried the effect of carbonate of soda on several waters, and find that in all cases it either completely suspends or greatly reduces the activity.

According to some authorities, alkaline waters, such as that obtained from artesian wells in the London basin, have a strong action on lead, but this is entirely contrary to my experience; and having

occasion recently to analyse one of these alkaline waters,* from a boring through the London clay, I also investigated its action on lead, and found it to be wholly without action on either the new or old metal. It should be mentioned that these alkaline waters are also specially rich in silica.

The effect of carbonate of soda on the activity of water at higher temperatures was also investigated.

Some of the "A" water alone, and some of the same water with an addition of 10 parts Na_2CO_3 per 100,000, were respectively placed in contact with pieces of old and new lead, and kept at 100° C. on a water-bath for about six hours. The water was then in each case examined for lead:—

"A" water after six hours at 100°	New lead. 2·80 parts Pb.
	Old lead. 2·80 " "
"A" water + 10 parts Na_2CO_3 per 100,000 after six hours at 100° C.	New lead. ·16 " "
	Old lead. ·25 " "

It is thus evident that the carbonate of soda acts as a very perfect protective at higher temperatures also.

Effect of Lime on the Activity of Water.—In order to ascertain whether carbonate of soda might not be replaced by the cheaper material, lime, a number of experiments were made with the latter, the following results being obtained:—

"A" WATER (FEBRUARY SAMPLE) + 2 PARTS CaO per 100,000.

XV.	XVI.
¾-in. New Pipe.	¾-in. Old Pipe.
Average daily amount of lead found during 11 days' trial.	
·08	·76

Owing to the unfavourable results thus obtained in the case of the old pipe, further experiments were made with the April sample from the "A" reservoir, which, as before mentioned, was considerably more active than the February sample, and with larger additions of lime. Thus:—

"A" WATER (APRIL SAMPLE) + 5 PARTS CaO per 100,000.

XVII.	XVIII.
¾-in. New Pipe.	¾-in. Old Pipe.
Average daily amount of lead found during 11 days' trial.	
·39	3·35

The above results show that, whilst the lime has practically the same protective action as carbonate of soda with new pipes, it actually increases the activity of the water towards old pipes, when used in such large proportion as 5 parts per 100,000.

Effect of Sodium Phosphate on the Activity of Water.—Among the substances which are generally accredited with the power of protecting lead, none enjoys perhaps such a high reputation as phosphoric acid. In order to determine whether the activity of the "A" water would yield to this material, experiments were made in which different proportions of hydric disodic phosphate were added to the water. The following results were obtained:—

* The alkalinity was equivalent to 19·8 parts Na_2CO_3 per 100,000.

"A" WATER (APRIL SAMPLE) + HNa_2PO_4

XIX.	XX.
$\frac{1}{2}$ -in. New Pipe.	$\frac{1}{2}$ -in. Old Pipe.
*1 Part P_2O_5 added.	*1 Part P_2O_5 added.
Average daily amount of lead found during 3 days' trial.	
2'60	2'50
*5 Part P_2O_5 added.	*5 Part P_2O_5 added.
Average daily amount of lead found during 3 days' trial.	
2'47	2'10
2'0 Parts P_2O_5 added.	2'0 Parts P_2O_5 added.
Average daily amount of lead found during 2 days' trial.	
*00	1'40

Thus, until very considerable proportions of the sodium phosphate are added, practically no diminution in the activity of the water results.

The Effect of Filtration on the Activity of Water on Lead.—In dealing with the active water of Huddersfield, Messrs. Crookes, Odling, and Tidy found that the activity was greatly reduced by filtration through a stratum of sand, carbonate of lime, and flint, and they attribute the diminished activity of the filtered water to a small proportion of silica dissolved from the flint. As these experiments have, as far as I am aware, not been repeated by any other observers, it appeared of particular interest to examine the efficiency of this method of treatment on the active water in question.

The filters were in the first instance constructed of 1 ft. 3 in. black limestone at the base; upon this followed a layer of 1 ft. 3 in. of flint, and upon this a stratum 2 ft. in thickness of fine silver sand. This filtering medium was arranged in a glass tube about $\frac{1}{4}$ in. internal diameter, and the water was always passed through at a rate not exceeding 50 gallons per square foot of filter-area per 24 hours. This filter is referred to below as "Filter No. 1."

The effect of filtration through this filter will be apparent from the results recorded below:—

XXI.	XXII.
"A" Water (April Sample), before Filtration.	"A" Water (April Sample), before Filtration.
$\frac{1}{2}$ -in. New Pipe.	$\frac{1}{2}$ -in. Old Pipe.
Average daily amount of lead found during 10 days' trial.	
2'06	1'54
This Tube was then filled with "A" Water after passing through No. 1 Filter.	This Tube was then filled with "A" Water after passing through No. 1 Filter.
Average daily amount of lead found during 3 days' trial.	
*37	*97

Thus the activity of this water before and after filtration presents a very strong contrast, but especially in the case of the new tube.

The experiment was then reversed; similar tubes were first filled with the filtered and afterwards with unfiltered water. Thus:—

XXIII.	XXIV.
"A" Water (April Sample), after passing through No. 1 Filter.	"A" Water (April Sample), after passing through No. 1 Filter.
$\frac{1}{2}$ -in. New Pipe.	$\frac{1}{2}$ -in. Old Pipe.
Average daily amount of lead found during 10 days' trial.	
*57	1'28
The Tube was then filled with unfiltered "A" Water.	The Tube was then filled with unfiltered "A" Water.
Average daily amount of lead found during 3 days' trial.	
2'43	2'33

Thinking that perhaps the efficiency of the filter depended mainly upon the carbonate of lime, a second filter (No. 2 Filter) was constructed, in which the layer of limestone was increased to 2 ft. 9 in., whilst the stratum of silver sand was reduced to a depth of 6 in. No. 2 filter was thus composed of—

Sand, 6 in. at the top.
Flint, 1 ft. 3 in.
Limestone, 2 ft. 9 in. at the bottom.

The following results were obtained in similar experiments made with this filter:—

XXV.	XXVI.
"A" Water (April Sample), after Filtration through No. 2 Filter.	"A" Water (April Sample), after Filtration through No. 2 Filter.
$\frac{1}{2}$ -in. New Pipe.	$\frac{1}{2}$ -in. Old Pipe.
Average daily amount of lead found during 10 days' trial.	
*32	2'33
The Tube was then filled with "A" Water after Filtration through No. 1 Filter.	The Tube was then filled with "A" Water after Filtration through No. 1 Filter.
Average daily amount of lead found during 5 days' trial.	
*34	1'62

It thus appears that the efficiency of the filter was by no means increased by increasing the thickness of the stratum of limestone and diminishing that of sand, but, on the contrary, the efficiency of this No. 2 filter was very much less, as shown by the strong action of the filtered water on the old lead pipe.

Although there is this marked difference between the activity of the water before and after filtration, it is very difficult to assign any adequate cause for the contrast. Thus the silica in the water before and

after filtration was practically identical, and was not increased, even after undergoing a second filtration :—

"A" water (April sample), before filtration contained 50 part SiO_2 per 100,000.

Ditto after passing once through No. 1 filter contained 52 part SiO_2 .

Ditto after passing twice through No. 1 filter contained 50 part SiO_2 .

In similar experiments made with a sample of "A" water, collected in June, I have also found that the silica was not increased by filtration through No. 1 filter. Thus:—

"A" water (June sample) before filtration, $\text{SiO}_2 = \cdot 82$ Part.

Ditto after passing through No. 1 filter, $\text{SiO}_2 = \cdot 78$

In this case the total hardness was increased by filtration from 6.7 to 7.0 parts per 100,000.

In the case of a water from Haverfordwest, which however had practically no action on lead, but which I had occasion to submit to filtration through a single layer of fine sand 2 ft. in depth, I found a very slight increase in the proportion of silica. The composition of this water, before and after filtration, is recorded below :—

RESULTS OF ANALYSES in PARTS per 100,000.

Haverfordwest Water.		
	Before Filtration.	After Filtration.
Total solids.....	8.56	8.40
Organic carbon.....	.196	.180
" nitrogen.....	.011	.011
Ammonia.....	Trace.	0
Nitrogen as nitrates and nitrites.....	.013	.011
Chlorine.....	2.4	2.4
Hardness, temporary.....	0	0
" permanent.....	2.6	2.6
" total.....	2.6	2.6
Silica.....	1.52	1.62

In subsequent experiments made in conjunction with Mr. Frew (*see* page 247), I have shown that when distilled water is slowly filtered through *extremely* finely divided flint, a small proportion (.15 part per 100,000) of silica is taken up by the water.

There appears also to be no material difference in the proportions of the dissolved gases present in the waters before and after filtration, although there is *some slight evidence* that the carbonic anhydride undergoes a small increase, and the oxygen a small diminution during the process. This would, of course, according to the explanation of activity given by Graham, Hofmann, and Miller, tend to reduce the activity of the water after filtration. Thus:—

DISSOLVED GASES in 100 Vols. of "A" WATER (JUNE SAMPLE).

	Before Filtration.	After No. 1 Filter.
CO_2	Vols. 190	Vols. 183
O	.678	.677
N	1.396	1.410

	Before Filtration.	After No. 2 Filter.
CO_2	Vols. 191	Vols. 200
O	.618	.634
N	1.348	1.348

	Before Filtration.	After No. 1 Filter.
	I. Vols.	II. Vols.
CO_2	.200	.216
O	.784	.717
N	1.464	1.464

The dissolved gases in the April sample of "A" water, which was much more active than the June sample, were as follows :—

	Vols.
CO_2078
O.....	.777
N.....	1.601

Again, in the case of a sample of Loch Katrine water, kindly supplied to me by Prof. Mills, I found the dissolved gases before and after filtration through No. 1 filter to be:—

DISSOLVED GASES in 100 Vols. of LOCH KATRINE WATER.

	Before Filtration.	After No. 1 Filter.
	I. Vols.	II. Vols.
CO_2	.034	.031
O	.672	.681
N	1.433	1.431

This sample of Loch Katrine water had the following composition :—

RESULTS in PARTS per 100,000 LOCH KATRINE WATER.

	Parts.
Total solids.....	2.06
Organic carbon.....	.150
" nitrogen.....	.027
Ammonia.....	0
Nitrogen as nitrates and nitrites.....	0
Chlorine.....	.7
Hardness, temporary.....	0
" permanent.....	1.0
" total.....	1.0
Silica.....	.15

It is not a little remarkable that this sample of Loch Katrine water, although so extremely deficient both in silica and carbonic acid, had only a slight action on lead. Passage through No. 1 filter further reduced its activity, as seen from the following experiments :—

LOCH KATRINE WATER.

XXVII.	XXVIII.
Unfiltered.	After No. 1 Filter.
$\frac{1}{2}$ -in. New Pipe.	$\frac{1}{2}$ in. New Pipe.

	'21
	The Tube was then filled with Water twice filtered through No. 1 Filter.
Average daily amount of lead found during 15 days' trial.	Average daily amount of lead found during 9 days' trial.
'35	'15
The Tube was then filled with Water twice filtered through No. 1 Filter.	The Tube was then filled with unfiltered Water.
Average daily amount of lead found during 3 days' trial.	Average daily amount of lead found during 3 days' trial.
'12	'32

A similar reduction in the activity of the water was also effected by filtration through 4 ft. 6 in. of fine sand instead of the composite filter. After this filtration it yielded on analysis:—

	Parts.	
Total solids	2'40	} per 100,000.
Organic carbon	'116	
„ nitrogen	'026	
Silica.....	'17	

I have recently had occasion to examine also two Cornish waters which have a strong action on new lead. These waters, which were derived from Redruth and St. Austell respectively, had the following composition:—

RESULTS in PARTS per 100,000.

	Redruth Water.	St. Austell Water.
Total solids	12'88	7'20
Organic carbon	'037	'020
„ nitrogen	'009	'011
Ammonia	0	0
Nitrogen as nitrates and nitrites	'218	'176
Chlorine	3'0	2'5
Hardness, temporary.....	0	'6
„ permanent	5'0	3'9
„ total	5'0	4'5
Silica.....	'96	1'02

Not having sufficient of these waters at my disposal to examine their behaviour in service pipes, I placed them in contact with small pieces of new and old

lead of equal size in the ordinary way adopted for testing the action of water on lead.

Redruth water after 5 New lead.....	'80 part Pb.
12 hours Old „	'38 „
St. Austell water after 5 New lead.....	1'00 „
12 hours Old „	'36 „

The waters were also each of them treated with 5 parts of carbonate of soda per 100,000, and their action on old and new lead again similarly tested:—

Redruth water + 5 parts Na ₂ CO ₃ per 100,000 (after 12 hours)	New lead '04 part Pb. Old „ '06 „
St. Austell water + 5 parts Na ₂ CO ₃ per 100,000 (after 12 hours)	New lead '08 „ Old „ '02 „

Thus the activity of each of these waters yields to treatment with a small proportion of carbonate of soda.

In view of the great importance of this subject, it is highly desirable that all tests made as to the activity of water towards lead should be made under uniform conditions, so that the results may be strictly comparable.

It is also very important that in investigating the activity of water, the conditions which hold good in the actual distribution of water should be as closely imitated as possible, and from the results which I have brought before you this evening it will be at once apparent how necessary it is that the action of the water on old service pipes as well as on new ones should be carefully inquired into, as the action in the two cases may, as we have seen, be widely different. In fact there can be no doubt that the corroded interior of an old pipe exposes a far more extensive front for the attack of the active water than does the polished surface of a new one.

In order to render the conditions of experiment still more closely analogous to those existing in actual practice, I have in a more recent investigation undertaken, in conjunction with Mr. Frew, and to which I shall presently refer, submitted the water in contact with the lead pipes to a pressure of some 2½ atmospheres.

As regards the means available for counteracting the activity of potable water, there are obviously several different courses open which will recommend themselves according to the particular circumstances of individual cases.

Thus it will be seen from the above results that water from one and the same source may be possessed of very different degrees of activity towards lead at different seasons. This difference is doubtless due not only to variation in the *quantity* of organic matter present in the water, but also to variation in the *quality* of that organic matter, as well as to variation in the nature and amount of the saline ingredients.

In some cases the activity of water supplies may be conveniently counteracted by the admixture of an inactive and somewhat highly saline water in suitable proportions, as in the particular case referred to in this paper. It is, however, extremely noteworthy that the proportion of such a hard water, which must be added in order to neutralise the activity, may be greatly in excess of what one would be led to expect from theoretical considerations only. This method of blending, moreover, will in most cases not recommend itself, owing to the consequent deterioration of the water for steam purposes.

For simplicity, efficiency, and for the promptitude with which it can be applied, no method can compete with that of adding carbonate of soda in

suitable proportions, which may be varied according to the necessities of the water at different seasons.

Extremely remarkable is the protection secured by the filtration of the active water, a protection which does not appear to be adequately accounted for by the change effected in the proportion of any one ingredient present in the water, but which must probably be referred to the minute alteration in a number of the ingredients producing such an aggregate change in the character of the water that the activity is reduced in a marked degree. Thus the hardness undergoes a slight increase, as does the silica, and probably also the dissolved carbonic anhydride, whilst the organic matter, and probably also the dissolved oxygen, undergo a slight diminution.

The filtration of upland surface water, which is in general the offender as regards lead, is, of course, strongly to be recommended on other grounds, and although the process does in the first instance greatly reduce the activity of the water towards lead, it is very doubtful whether this protective action can be maintained without a frequent renewal of the filtering medium. In any case the activity of the water before and after filtration must be kept under constant observation.

It is further evident, from the results recorded in this paper, that although the chemical composition of a water indicates the probability or improbability of its acting on lead, recourse should still invariably be had to actual experiment in order to finally determine this point, whilst the seasonal variations in the character of surface waters should also be duly taken into consideration in such investigations.

There can be no doubt that in the past very insufficient attention has been devoted to the question of the safe distribution of these soft upland surface waters through leaden pipes, their freedom from any suspicion of sewage contamination having led to their enthusiastic recommendation in all quarters. Now, although I do not for a moment wish to suggest that these waters are not of the most excellent quality, especially for the supply of manufacturing towns, still it would appear to be high time that every regard should be paid to their distribution at a minimum risk to the consumer.

RESULTS of ANALYSES expressed in PARTS per 100,000.

— Dundee Water.		Total Solids.	Hardness.			Silica.
			Temporary.	Permanent.	Total.	
1889.						
I.	Jan. 24.....	4.0	6	3.7	4.3	65
II.	Feb. 27.....	7.6	0	6.1	6.1	60

When introduced into new pipes, however, the water has in the first instance a very considerable action on the metal. Thus two new leaden tubes 2 ft. by $\frac{3}{4}$ in. were filled with the above sample No. I, and the lead in suspension and solution determined from day to day:—

Number of Hours during which Water remained in contact with Lead.	Tube I.		Tube II.		Tube III. 10 Parts Na_2CO_3 .		Tube IV. 5 Parts Na_2CO_3 .	
	Lead in Parts per 100,000.							
Hours.								
24	2.72	2.86	
24	2.90	2.88	
66	2.30	2.32	
24	2.46	2.33	
24	2.39	2.15	During the latter half of these experiments, the same water to which 5 and 10 parts respectively of carbonate of soda per 100,000 had been added, was placed in two similar new tubes, and the lead from these simultaneously determined thus:—					
24	2.20	2.20						
24	2.17	2.11						
68	2.13	2.07						
24	2.03	2.05		2.16				2.14
24	2.13	2.12		2.06				2.14
42	2.09	2.15		2.07				2.08
70	2.06	2.11		2.06				2.11
46	2.10	2.13		2.06				2.11
24	2.09	2.14		2.05				2.15

N.B.—In all the experiments recorded in this paper leaden pipes 2 ft. in length and $\frac{3}{4}$ in. internal diameter were used.

The above results show that although this Dundee water has a very strong action on new lead in the first instance, the action rapidly diminishes, and soon becomes insignificant. The experiments with carbonate of soda, moreover, show that by the addition of this substance to the water in the above proportions, even this initial action is entirely done away with, thus confirming the results previously obtained by one of us with other waters.

The Action of Water containing Ammonium Nitrate.—Wishing to render the Dundee water more active for the purpose of some other experiments, we prepared samples of this water* to which 2 and 10 parts respectively of ammonium nitrate had been added, inasmuch as this salt is generally supposed to cause the solution of lead. (M. M. P. Muir, J. Chem. Soc. 1877.)

To our surprise, however, we found that on filling the lead pipes with these waters the amount of action was actually less than in the case of the Dundee water alone, and less in the case of the sample to which 10 parts of ammonium nitrate had

* Collected, February 27, 1889; for analysis, see above.

FURTHER EXPERIMENTS ON THE ACTION OF WATER ON LEAD.

BY PERCY F. FRANKLAND, PH.D., B.Sc., ETC., AND WILLIAM FREW (Student in the Chemical Laboratories of University College, Dundee).

In continuation of the previous experiments made by one of us on the action of water on lead, we have extended these investigations with a view to further testing the protective action of various substances, as well as to ascertain the effect of bringing different kinds of water into contact with the metal at a high pressure.

In the first instance we made some experiments with the water supplied to Dundee. This water, although obtained from an upland gathering-ground, soft, and in fact often quite destitute of temporary hardness, has no permanent action on lead. Thus:—

been added than in that which had received only two parts.

Effect of Pressure on the Action of Water on Lead.—In order to test the action of water on lead under pressures greater than that of the atmosphere, we made use of the following apparatus:—

A large U-tube of glass (A) is fastened to a board bearing a scale of feet and inches. The lower end (B) of the U-tube is connected by a piece of thick walled india-rubber pressure-tubing to a glass tube passing through one of the perforations of an india-rubber stopper, through the other perforation of which passes a stoppered funnel (C). The leaden pipe (D) is filled with the water under examination, the india-rubber stopper is then inserted and held firmly in position by means of the clamp and stand (E). More of the same water is then introduced through the funnel (C) until it flows over into the U-tube and passes beyond the bend (F). The stop-cock of the funnel is then closed and mercury is poured in at the open upper end of the U-tube until the desired pressure is obtained. At the end of the experiment the india-rubber joint is closed with a clip at (B), the leaden tube disconnected, and the water poured out for testing.

In the first instance we submitted the sample of Dundee water collected on January 24th, 1889, and the analysis of which is given above, to examination with the following results:—

—	Hours in Contact.	Temp. ° F.	Tube XI. Pb per 100,000.	Total Pressure on Water, including that of the Atmosphere.
1889, Feb. 11	66	43-40	0	90 inches of mercury.
" 13	46	41-43	0	66 " "
" 14	24	43-44	0	83 " "
" 15	24	44-45	'09	Atmospheric pressure only.

From the above experiments it appears that under a high pressure the Dundee water takes up no lead either in solution or suspension, even from a perfectly new tube; and further than this, that the tube which has been submitted to the water under pressure in this manner for several days is as much protected against further action as a tube which has been in contact with the same water under atmospheric pressure for a considerably longer period of time, as is seen from a comparison of the last result in the above table with the results recorded for the same water in the first table of this paper.

Distilled Water under Pressure.—Experiments were then made with the same apparatus, using distilled water instead of Dundee water; the distilled water was in each case also simultaneously placed in an ordinary lead tube under atmospheric pressure.

The following results were obtained:—

Date.	Hours in Contact.	Temp. ° F.	Tube XII. Atmos. Pressure.	Tube XI.	Total Pressure including Atmosphere.
			Pb. '04 parts	Pb. '05 parts	92 in. of mercury.
1889, Feb. 18	2	45	'15 "	'30 "	78 " "
" 18	3	45	'80 "	1'30 "	90 " "
" 20	5	47	4'17 "	5'00 "	78 " "

It thus appears that the activity of the distilled water is distinctly greater under increased pressure.

Further experiments were then made with the view of ascertaining whether the gases (oxygen and carbonic anhydride) dissolved in the distilled water exercised any influence on the activity of the water, both at ordinary and at increased pressures. For this purpose the distilled water was first boiled for one hour, then rapidly cooled, and then a stream of carbonic anhydride or oxygen passed through it for two hours. With distilled water thus saturated the following results were obtained at atmospheric pressure:—

Date.	Hours in Contact.	Temp. ° F.	Tube VII. saturated with CO_2 .	Tube VIII. saturated with O.
			Pb. 1'30 parts	Pb. '32 parts
1889, March 8	20	44-45	1'80 "	'24 "
" 9	20	45-43	This tube was now filled with a mixture of equal volumes of the water saturated with CO_2 and O.	
" 12	20	43-45	Pb. 1'50 parts	Pb. '28 parts
" 11	20	48-47	1'43 "	'15 "
" 15	20	47	'90 "	" "

Thus the distilled water saturated with carbonic anhydride is very much more active than that saturated with oxygen, although much less active than ordinary distilled water, whilst the mixture of the two waters in equal volumes does not differ materially in its activity from that of the distilled water saturated with carbonic anhydride only, but is much less active than ordinary distilled water.

Distilled water thus saturated with these gases was then placed in lead tubes under increased pressure with the following results:—

DISTILLED WATER SATURATED WITH OXYGEN.

Date.	Hours in Contact.	Temp. ° F.	Tube XIV. Atmospheric Pressure.	Pressure. Tube XIII.	Total Pressure including Atmosphere.
1889. Mar. 14	16	48—46	Pb. '10 part	Pb. 0	84 in. mercury.
" 15	20	47	'17 "	Very slight trace.	90 " "

DISTILLED WATER SATURATED WITH CARBONIC ANHYDRIDE.

Date.	Hours in Contact.	Temp. ° F.	Tube XVI. Atmospheric Pressure.	Pressure. Tube XV.	Total Pressure including Atmosphere.
1889. Mar. 15	18	48	Pb. 2'30	Pb. 2'80	84 in. mercury.
" 16	4	48	2'00	1'60	90 " "

These experiments show that the distilled water saturated with oxygen only, and which is only faintly active under ordinary atmospheric pressure, becomes actually inactive under increased pressure, whilst the distilled water saturated with carbonic acid undergoes but little alteration, as regards its activity, on increasing the pressure within the limits employed by us.

The Effect of Filtration through Siliceous Material.—We have also made some further experiments on this subject, with the special object of ascertaining to what extent silica is dissolved when the siliceous material is presented to the water in an extremely fine state of division.

For this purpose some flint was finely powdered, and only that portion passing through a sieve with 28 meshes to the linear inch was used for experiment. The powder thus obtained was first digested with hydrochloric acid to remove any iron that might have gained access to it during the process of pulverisation, after which it was thoroughly washed and then placed in a glass tube '75 inch in diameter, so as to form a compact filtering stratum 35 inches in height. The particular water under examination was then passed through this filter at a rate not exceeding 50 gallons to the square foot in 24 hours.

The Effect of Filtration on Dundee Water.—This water was passed through the filter at the rate of 26 gallons per square foot in 24 hours. The same water, both before and after filtration, was then placed in new lead tubes, and the lead present, both in suspension and solution, determined, with the following result:—

Date.	Hours in Contact.	Temp. F.	Tube V. Filtered Dundee Water.	Tube VI. Unfiltered Dundee Water.
1889. March 8	24	45—46	Pb. '20 parts	Pb. '16 parts
" 9	24	46—45	'18 "	'23 "
" 11	42	45—43	'22 "	'17 "
" 12	24	43—45	'18 "	'15 "
" 13	24	45—48	'19 "	'20 "
" 14	24	48—47	'15 "	'17 "

SiO₂ in unfiltered water = '60 parts per 100,000.

" filtered " = '75 " "

From the above it appears that the filtered water had from the first less action on lead than the unfiltered, but that the action of the two became rapidly equalised.

The proportion of silica was distinctly though slightly greater in the filtered than in the unfiltered water.

The Effect of Filtration on Distilled Water.—This water was passed through the same filter at the rate of 35 gallons per square foot per 24 hours. The filtered and unfiltered waters were then compared in similar new lead tubes, with the following result:—

Date.	Hours in Contact.	Temp. F.	Tube IX. Filtered Distilled Water.	Tube X. Unfiltered Distilled Water.
1889. March 15	20	47	Pb. '25 part	Pb. 4'20 parts
" 16	20	..	'28 "	7'60 "
" 19	24	..	1'50 "	6'00 "
" 20	22	..	1'30 "	4'40 "
" 21	22	..	Fresh Sample of Water. '95 part	Fresh Sample of Water. 4'40 parts

SiO₂ in unfiltered distilled water = '000 part per 100,000.

" filtered " = '15 " "

Thus the difference in the activity of the distilled water before and after filtration is extremely pronounced, whilst the difference in the proportion of silica before and after filtration is identical with that previously found in the case of the Dundee water.

Thinking that possibly the difference in the activity before and after filtration might be occasioned by some alteration taking place in the nature and amount of the dissolved gases in the water during the process of filtration, we made a number of determinations of these gases in both samples of water, but without being able to establish any material difference between the two.

The principal results we have arrived at in the course of our investigation are:—

- (1.) That the activity of water towards lead may, according to its composition, be either increased or diminished by increased pressure.
- (2.) That water containing oxygen has its activity diminished, whilst the activity of water containing carbonic acid is not materially affected by such increased pressure as we employed.
- (3.) That by very slow filtration through extremely finely-divided flint a small proportion of silica is dissolved.

- (4.) That the water after such filtration has less action on lead, both in the case of distilled water and other soft potable waters that have been submitted to examination.
- (5.) That the activity of soft water is very materially reduced by the addition of small proportions of carbonate of soda.

Finally we would call attention to the great importance of invariably submitting waters to the pressure-test described, so that the conditions found in actual practice may as far as possible be reproduced.

DISCUSSION.

The CHAIRMAN said that the question of the pollution of water by lead was one of primary importance, and it was a matter which proved the utter worthlessness, and indeed danger, of a moderate knowledge of chemistry. He had been taught in his youth that if there was one thing in chemistry which was thoroughly understood, it was the reasons for the contamination of water by lead. Yet, after a century of such knowledge, it was found that very little was really known about the matter. So far as recent work had yet gone, it suggested that the cause of the evil was organic rather than inorganic; but what was the exact cause of the action of peaty waters on lead appeared to be one of the most obscure problems of the day. These waters of very small temporary hardness and absolute freedom from contamination would be sought for as the very best for drinking purposes but for their unfortunate capacity for dissolving lead. He would like to ask whether the mixture of "A" water and colliery water described by Dr. Frankland had been allowed to stand for any considerable time, or whether it was put into the lead pipe at once; and also whether the amount of soda added was sufficient to produce a permanent precipitate. If so, it was possible that not only were the bases precipitated, but also some of the slightly soluble organic acids which were the possible cause of the mischief.

Dr. THOS. STEVENSON regarded the communication as a valuable contribution to our knowledge of the action of water on lead and of lead upon water. He was sorry to find, however, that the author had not directed attention to the question at one point, viz., the acidity of the water. However, as Mr. Allen was present and had specially studied the effects of the acidity of these upland surface waters, and the relative actions on lead of acid and non-acid upland waters, no doubt the meeting would derive some valuable information from him on that point. This point was brought forcibly to his mind in considering one of the remedies for the action of such waters on lead—the addition of carbonate of soda. It would have been interesting to have known with respect to the "A" water whether there was any free acid, either organic or inorganic, which could have been neutralised by the carbonate of soda. Dr. Frankland had not found that lime—which should have been equally effective, if added in sufficient quantity—had the same action as carbonate of soda in preventing the reciprocal action of water and lead. This was a point which ought to have an important bearing upon Dr. Frankland's calculation of the temporary hardness of the mixture of the "A" water with water that had temporary hardness. Of course if the "A" water, having no temporary hardness, were an acid water, its mixture with the colliery water would not give the amount of temporary hardness recorded by Dr. Frankland. Those figures must therefore, for the present, be regarded as somewhat hypothetical. His own experiments

with regard to the action of silica, flints, and lime upon water agreed with those of Dr. Frankland. The amount of silica which went into solution on filtering water through siliceous material was very small, and did not seem to have much effect in diminishing the action of water upon lead. There was always one great mechanical difficulty in testing waters for this action—a difficulty which Dr. Frankland had overcome to some extent, but not entirely. In testing the water one must use either a fresh lead pipe or one that had become tarnished. If one used fresh pipe, two pipes, or two portions of one pipe, would not agree in the character of their surface. It was impossible to get them exhibiting exactly the same kind of surface. One pipe would be rougher than another; and if the operator attempted to clean them he at once got a different surface. The action of water upon a new pipe was not a fair guide to what its action would be on a pipe in actual use. He was therefore glad to see that Dr. Frankland had tested with pipe that had been used with the waters under examination; otherwise it would be impossible to say whether the water would have more or less action on an encrusted pipe than on fresh lead. Similarly, if one took a pipe encrusted by one water and passed another water through it, one could not predict the action of the new water on another pipe. It was therefore desirable, though not always possible, to employ in these experiments the pipes actually used for the given waters. Another difficulty had been created in his mind by Dr. Frankland's statement that he cleaned his pipes with caustic soda to free them from grease and then passed tap-water through them for some hours. That was a method he hardly approved of. For if Dr. Frankland cleaned the pipe by using strong soda, and then passed through it water which would itself cause a slight incrustation, he could not be said to have acted on a new pipe or on an old pipe encrusted by the water operated on. One interesting result of his experiments on these waters was to show that the silica hypothesis did not hold good. It was seen that Loch Katrine water acted on lead to a very slight extent though it was very free from silica; and in Dundee also they had a water which fell a little below Dr. Tidy's standard of silicated water, and yet appeared to act on lead much as the Loch Katrine water did. He hoped that Dr. Frankland would be able to inform the meeting whether he had tested these waters for free acid. According to his own experience, those waters which were free from temporary hardness were frequently, if not generally, also distinctly acid, containing sometimes as much as nearly one part per 100,000 of free acid calculated as sulphuric acid, part of it being an inorganic acid and part organic, as shown by the residue, after accurate neutralisation, evaporation, and incineration, containing carbonates.

Mr. WM. FOSTER said that it had occurred to him that perhaps the variations in the first series of experiments might be explained by the ratio of volume to surface. Or perhaps air might have gained access in some way. It seemed to him extraordinary that there should be such variation in the action of water on lead pipes which were supposed to be similar in every respect. It was a most important question, and one which it was often extremely difficult to answer definitely, whether a particular water should be condemned or not. Within the last fortnight he had heard of a case of lead poisoning in the county from which he presumed these waters came. In that case, however, the water was found to be exceptionally hard and free from lead.

Mr. A. H. ALLEN said that he would be glad if Dr. Frankland would answer Dr. Stevenson's question as to the acidity of the "A" water at this point, as his own remarks would to a great extent depend on the nature of that reply.

Dr. FRANKLAND said that the water was practically neutral. At any rate, if there was any acidity it was so slight that it could not be determined by the ordinary methods, and the carbonate of soda added in the experiments must have been enormously in excess of any trace of acidity that may have been present.

Mr. A. H. ALLEN, continuing, said that if that was the case, he would like to know how Dr. Frankland had tried to estimate the acidity, if any. He could not agree that the acidity might be so slight as not to be worth determination. There was often only one-half or even one-quarter of a part of free acid, expressed in terms of sulphuric acid, per 100,000; but that was a sensible amount of acidity, capable of acting on lead to a notable extent. Assuming that the free acid had the same molecular weight as lactic acid, in presence of oxygen it would act on more than its own weight of lead. It would also act on oxide of lead. Chemists had talked much nonsense in the past about the solubility of salts of lead. Sulphate of lead, for example, had been regarded as an insoluble salt. But in this connexion and for this purpose it must be regarded as soluble, seeing that a gallon of water dissolved about 3 grains of the salt, equivalent to 2 grains of metallic lead. Similarly, the acidity of water was often regarded as meaning several grains per gallon or several parts per 100,000; but those were extravagant amounts. One had to deal in practice with much smaller quantities—quantities that could not be detected by blue litmus paper applied in the rough and ready manner that was sometimes done. But if one took the water and evaporated it to one-tenth its volume, any acid then found was clearly not carbonic acid. In the case of one water that he had had much to do with—part of the Sheffield supply, which was very similar in character to the water that Dr. Frankland had described, and, like it, had a considerable action on lead—the free acid was clearly a fixed organic acid, for it was not removed by concentration and did not act on methyl-orange. On the other hand it did act on phenolphthalein, and the amount present could be accurately determined in terms of sulphuric acid by titrating the concentrated water with caustic alkali; and when the previously neutralised water was evaporated to dryness and the residue ignited, a carbonate was formed, which showed the previous presence of an organic acid. Again, Dr. Frankland had said that the "A" water had no temporary hardness. But how did he ascertain that? Evidently the ordinary method by means of soap solution was unfit for determining an amount of temporary hardness of less than $\frac{1}{2}$ grain per gallon. Such quantities could only be detected by evaporating to a small bulk, filtering, and testing the insoluble matter for earthy carbonates. With regard to the lead pipe experiments, he did not approve of the method of taking a piece of new pipe and keeping water in it for a certain time, and then taking the water out and ascertaining the amount of lead. Mr. Allen here described and illustrated on the blackboard the method and apparatus which he himself employed for such examinations of water. He did not think that lead pipe could with certainty be cleaned by means of soda; and by washing afterwards with distilled water for several hours one was likely to get a film of oxide.

Dr. FRANKLAND explained that he had used and stated tap-water only.

Mr. ALLEN said that was worse. After each experiment the pipe was exposed to the air. No wonder, then, that lead was dissolved. Air should never be allowed to enter the pipe, which should be kept, as far as possible, under the conditions of actual practice. The experiments under pressure described by Dr. Frankland only went a little way. Dr. Sinclair White and he had made a few similar experiments under a pressure of 10 atmospheres by attaching the tube to the high-pressure service. The results, however, were not so striking as to lead them to suppose that pressure diminished the activity of water upon lead; in fact, in the few trials made, an increased effect was observed. [Mr. Allen here illustrated the method and apparatus for his experiments under pressure-supply.] He did not see any mathematical or chemical reason for the great difference between the results with $\frac{1}{2}$ -in. and with $\frac{3}{4}$ -in. pipe. Other things being equal, he would have expected more action in the narrower pipe. In a wide pipe there was a certain amount of action round the interior surface, but the inner portions of the water never got into contact with the surface; whereas in a narrower pipe there was much less tendency to the formation of such zones. With regard to silica—he had made many experiments in the hope of introducing it into water; and it had been proposed by Messrs. Crookes, Odling, and Tidy to carry out an experiment with silica and limestone at Sheffield on an enormous scale and at an expense to the inhabitants of 100,000%. But considering that it would be rash to commence with such extensive operations, he had made a number of experiments on a small scale. He had taken distilled water and Sheffield high-level water and kept them in contact with fragments of limestone, natural flint, and decalcified flint for from 48 to 72 hours, but he never could succeed in introducing silica to a greater extent than $\frac{1}{2}$ grain per gallon. When he tried the effect on a new lead pipe, both the calcified and silicated water acted strongly at first, but he found that in the case of the limestone the action gradually decreased, and in about 10 or 11 days ceased altogether. The same thing happened in the case of natural flints. But natural flints were not purely silica; they were silica, with an outside coating of silicate of calcium. When this coating was dissolved or decomposed by hydrochloric acid the flint had no action on the water, the water corroding lead as freely after a month as the first day. Dr. Tidy had attributed the action of limestone to the silica in it. However that might be, it was an interesting fact that this combination of silica and lime did seem to have a certain effect in restraining the action of water on lead; but he himself attributed it more to the limestone, for it was evident that if due to the small proportion of silica present, it would be necessary to dissolve such an amount of lime as would render the water intensely hard in order to get the half grain of silica per gallon which Dr. Tidy fixed as the amount necessary to prevent action on lead pipes. He was sorry that Dr. Frankland had not applied his lime and carbonate of sodium in a more systematic manner. If, instead of merely adding 5 parts per 100,000, he had exactly neutralised any free acid which might have existed in the water, and not added an excess of alkali, it would have been more satisfactory. At any rate he should have liked to have learned the result of an experiment conducted in that way. Adding the carbonate in excess of that necessary to just neutralise the acid was perhaps prejudicial. Mr. C. Rawson, of Bradford, had recently read a paper before the

Society of Dyers and Colourists, in which he stated that he had found that carbonic acid had a violent action on lead. That was also the experience of aerated water makers, but it was opposed to Dr. Frankland's experiments, and, he thought, to his father's statements also. He (Mr. Allen) had experimented with phosphates in water with very satisfactory results, and so, independently, had Mr. Rawson. They had found that water containing a trace of phosphates had no action on lead, as pointed out long since by Dr. Edward Frankland; and if the water contained lead, all that was necessary was to pass it through an animal charcoal or bone-ash filter, and the whole of the lead was removed as a highly insoluble phosphate of lead. He had actually taken out provisional protection for a filter consisting of phosphatic material other than animal charcoal. At Sheffield it was the acid water that acted on the pipes, and the neutral water did not; and exactly the same occurred at both Huddersfield and Bradford. So that whether the action of the water examined by Dr. Frankland was or was not due to acidity, it was at any rate a fact that special activity of that description had frequently been found associated with the presence of free acid in the water. At Bradford, they had cured it by mixing the hard and soft waters together; in other words, as he had suggested, by neutralising the free acid contained in the soft water.

The CHAIRMAN, in calling upon Dr. Frankland to reply, said that he also had been perplexed by the figures indicating a greater action of the water on the pipes of the larger diameter. Bearing in mind that the area of a pipe varied as the square of the dimensions, whereas the surface varied directly as the dimensions, the larger the pipe the less would be the proportion of the circumference to the area. He would therefore have expected a smaller proportionate reaction upon the larger pipe.

Dr. PERCY FRANKLAND, in reply, said that he had himself expected to get more lead in proportion from the half-inch pipes than from the three quarter inch pipes; but the fact remained that the smaller pipes almost invariably gave smaller quantities than the larger ones. Whether or not the results might be due to some mass action, he could not say. It showed, however, how necessary it was in tests of this kind to use pipes of the same diameter. In reply to the question as to whether the waters were allowed to stand after the addition of carbonate of soda, he would point out that although some samples were probably used on the same day that the addition was made, still they would have stood for about a fortnight before the experiments were concluded, because all the results tabulated were averages of about 14 days' trial. With regard to the questions of Dr. Stevenson and Mr. Allen as to the acidity of the "A" water, it was a water which under ordinary circumstances would be described as practically neutral, and even when tested with phenolphthalein the acidity was hardly perceptible.

Mr. ALLEN asked whether that was before concentration, as, in that case, it might be carbonic acid.

Dr. FRANKLAND, continuing, said the water would certainly have been described by any ordinary analyst as neutral. But he knew Mr. Allen made a great point of acidity, and tested for it with exceptional care. Exception had been taken to his method of cleaning the pipes. He could only say that he would be very glad to hear of a better method. To wash a pipe with soda was the ordinary way of removing grease; and that tap-water did not injure the lead was shown by the fact that lead would

remain bright for hours in London water. With regard to the Sheffield pressure experiments which Mr. Allen had described, he would have been glad to have exposed the waters under notice to that pressure of 10 atmospheres, but it was impossible in this case. In all tests of the action of water on lead it was desirable that experiments should be made under pressure. He was convinced that water acted on lead very differently under high pressure and under ordinary pressure, and that a water which might be condemned when tested at atmospheric pressure would be found to have very slight action on lead if tested at high pressure, and perhaps *vice versa*. In the case of Glasgow water, it was found some years ago that when the pipes were charged intermittently the water acted upon them strongly, but on the introduction of the constant service that action on the lead practically vanished. The flints used in his later experiments with distilled water were washed in hydrochloric acid, and the acid was then completely washed out. So that it would seem that contact with the flint did produce some effect upon the water.

THE ECONOMY OF PURE CAUSTIC SODA.

BY C. F. CROSS AND E. J. BEVAN.

IN the course of the examination of a number of samples of caustic soda intended for use in paper-making, we observed that in titrating certain specimens they gave very varying results, according to the particular indicator employed. Thus, in one case a sample that "tested" 60.73 per cent. with litmus, gave 64.70 per cent. when titrated with acid in presence of methyl-orange. This large difference we subsequently found to be due to the presence of about 3 per cent. of alumina.

When such a caustic is titrated hot in presence of litmus, the final point is reached when the whole of the alkali present has been saturated with acid, and the alumina has commenced to precipitate. This is, of course, in accordance with the fact that sulphate of alumina is acid to litmus.

When, however, methyl-orange is used, the final point is not reached until not only is the soda saturated, but the precipitated alumina is re-dissolved, sulphate of alumina being neutral to methyl-orange.

The fact that alumina can be titrated with standard acid in presence of methyl-orange is not new, having been pointed out in the excellent papers on the use of indicators by Robert T. Thomson (Chem. News, 1883 and 1884), but its bearing on the valuation of commercial caustic soda has, we think, been overlooked. Even in such a work as Lunge and Hurter's "Alkali-makers' Pocket-book," where one might reasonably expect to find it, no mention is made of the fact. Although the proportion of alumina in commercial caustic (excepting caustic bottoms) is usually small, and, therefore, of small influence upon the results of its industrial application, it often exceeds the limit of a negligible quantity. We shall consider it first in regard to its analytical determination. Finding, in a number of cases, the differences between the titration with litmus and that with methyl-orange approximately proportional to the amount of alumina present, the suggested relationship was more closely investigated, as follows:—We prepared a solution of pure caustic soda, the strength of which was accurately determined. In

varying volumes of this solution we dissolved known quantities of pure precipitated alumina. The results of the various titrations are given in the following tables:—

	Cc. N. Acid consumed.		
	Litmus.	Phenolphthalein.	Methyl-Orange.
•496 soda alone	12•4	12•4	12•4
•496 soda + •084 Al ₂ O ₃	13•0	12•4	16•5
•496 soda alone	12•4	12•4	12•4
•496 soda + •16848 Al ₂ O ₃	13•0	12•4	20•1
1•24 soda alone	31•0	31•0	31•0
1•24 soda + •084 Al ₂ O ₃	31•9	31•0	35•0
1•24 soda alone	31•0	31•0	31•0
1•24 soda + •421 Al ₂ O ₃	33•0	31•1	51•4

The titrations with litmus were performed in the boiling solution in the usual way. In the case of phenolphthalein, the solutions were boiled with a slight excess of acid (about 0•5 cc.), and, after cooling, were titrated back with normal soda. In the case of methyl-orange, a slight excess of acid was added, and the solution titrated back in the cold.

It was found that under these conditions the final point, with litmus, was somewhat indistinct; with phenolphthalein the reaction was sharper and, as will be seen by the numbers given, satisfactory.

In a few instances cochineal was used as indicator, with nearly the same results as with methyl-orange, but the final point was less exact.

Assuming that the normal sulphate $\text{Al}_2\text{S}_3\text{SO}_4$ is formed before an acid reaction is produced, with methyl-orange as indicator, 1 cc. should be equal to •01716 grm. Al_2O_3 . Taking, however, the mean of the differences between the titration with phenolphthalein and methyl-orange, we find that 1 cc. of normal acid is equal to •0212 grm. of Al_2O_3 , corresponding to the molecular ratio $2\text{Al}_2\text{O}_3 : 5\text{SO}_3$.*

The results are summarised in the subjoined table, of which column I. represents the amounts of alumina added; column II. the amounts calculated from the mean equivalent in Al_2O_3 for 1 cc. of acid; and column III. the amounts calculated on the assumption that the normal sulphate is formed at the "neutral" point:—

I.	II.	III.
•0840	•0870	•0704
•0849	•0818	•0687
•1285	•1632	•1320
•4210	•4325	•3503
•4219	•4113	•3331

The value of •0212 Al_2O_3 for 1 cc. of normal acid is confirmed by the titration of recently-precipitated alumina alone with the acid. Thus, the mean of two such experiments gave the number •0210 for 1 cc. This equivalent is, moreover, independent of the acid employed. Thus, precisely similar results were obtained with normal sulphuric, nitric, and hydrochloric acids.

Thomson states (*loc. cit.*) that alumina can be titrated in presence of methyl-orange, and that

"about 100 per cent. is indicated." As, however, he gives no numbers, it is impossible to say to what extent we agree.

We next endeavoured to apply the method to the determination of alumina in different samples of caustic soda and in sodium aluminate. The following table contains the results obtained:—

	Caustic Soda.				Sodium Aluminate.
Percentage Al_2O_3 determined gravimetrically	0.70	1.40	2.40	2.78	20.59
Percentage Al_2O_3 determined volumetrically from difference between titrations with litmus and methyl-orange	0.62	1.35	2.32	2.84	20.90

As all the specimens of caustic examined by us contained considerable quantities of sodium sulphite, we investigated what influence, if any, this salt would have on the determination. For this purpose we prepared a solution containing known quantities of caustic soda, alumina, and sodium sulphite. Without troubling the Society with the analytical numbers, we will merely state that they showed that the sodium sulphite exercised no influence on the result. The same holds good with sodium thiosulphate.

The estimation of the exact amount of alkali in such a mixture as 60 per cent. commercial caustic soda is a matter of very great difficulty, and, as far as we know, no satisfactory method has been described.

If the sample contains, of the impurities dealt with in this paper, only sodium sulphite and no thiosulphate, the alkali can be determined fairly accurately in the following manner:—

A known weight is titrated with normal acid in the cold in presence of phenolphthalein. In this way the whole of the soda present as hydrate, together with rather more than one-half of that existing as carbonate, is estimated (titration A). In solutions containing only hydrate and carbonate the titration with phenolphthalein gives the hydrate and exactly one-half the carbonate; but this does not hold good in such a mixture as 60 per cent. caustic.

An excess of acid is now run in, and the solution titrated with standard iodine solution. As the presence of starch would interfere with the subsequent operations, we take the iodine solution as its own indicator. The solution is now boiled to expel carbonic acid, allowed to cool, and titrated back with normal soda, still using phenolphthalein as an indicator.

If much alumina be present, some little time must be given before the final point is decided upon. The total amount of acid consumed (that is, the original volume added) plus that calculated from the amount of standard iodine solution consumed and minus the equivalent of the alkali used in back titration, gives the total amount of soda present as hydrate and carbonate (titration B).

The difference between this and the original titration (A) gives a rough estimation of the soda existing as carbonate. In our experience it is invariably too low, being only about 90 per cent. of that actually present. The reason for adding a volume of acid equivalent to the iodine consumed is, that by the oxidation of sulphite into sulphate by means of iodine, an equivalent quantity of free acid is formed according to the equation:—

* This ratio would seem to indicate the formation of a new sulphate of alumina. This we propose to further investigate.

the amount to be added should, of course, be exactly equal to the volume of iodine consumed, or one-tenth in the case of decinormal iodine. It should be noted, however, that we find on oxidising pure sodium sulphite in this way the amount of acid formed is not quite equivalent to the iodine consumed. The difference, however, is so slight as to be unworthy of consideration in a commercial analysis.

The total soda and sulphite having been determined, methyl-orange is added and the same solution again titrated with normal acid. The final point is somewhat slow in arriving, and the better plan is to add an excess of acid and titrate back with normal soda, when a fairly sharp final point is obtained. The amount of acid consumed is calculated into alumina on the basis already given.

Such an easily conducted analysis will be found very useful in examining samples of caustic soda containing no thiosulphate. If this be also present a small error will be introduced due to the fact that when thiosulphate is oxidised by iodine only neutral salts are produced. Thus:—

As a further instance of the unreliability of methyl-orange as an indicator in testing for alkali, we may cite the following numbers obtained during an examination of the effluent from a paper mill:—

	Na ₂ O Grains per Gallon.	Indicator.
Effluent titrated direct.....	21·8	Methyl-orange.
	14·3	Litmus.

In order to ascertain which result gave the true amount of alkali, the effluent was evaporated to dryness, ignited, and the alkali determined in the solution of the residue. This method gave 14·3 grains per gallon, both with litmus and methyl-orange.

In concluding this part of our paper, we would briefly summarise the conclusions at which we have arrived:—

1. Neither methyl-orange nor cochineal can be used as indicators in testing for alkali in presence of alumina.

2. Of the two, phenolphthalein gives more reliable results than litmus. This will be seen on examination of Table I.

3. Alumina is determined with sufficient accuracy from the difference between the titrations with phenolphthalein and methyl-orange, taking 0·0212 as the equivalent of Al_2O_3 per cc. normal acid.

We now approach the main subject of our paper, viz., the economical advantages of the use of pure caustic soda. While we propose to discuss this mainly in relation to the use of caustic soda in paper-making, that is, for the isolation of cellulose from the various raw fibres, our conclusions will be found to have an equally direct bearing upon others of its industrial applications. Prior to the introduction of pure alkali in the form of ammonia soda, paper-makers were entirely dependent for their alkali on three distinct products, viz., 60 per cent. cream, 60 per cent. white, and 70 per cent. white. Of these, 60 per cent. cream was by far the most generally employed, and was to be preferred to 60 per cent. white as relatively purer, and, indeed, on the ground of proportionate expense, to 70 per cent. There were, in addition, other sources of alkali, such as the various soda-ashes, but these were generally less economical. We must also mention the pure caustic soda manufactured by the Greenbank Alkali Com-

pany, but this had only a theoretical interest for the large consumer, its price being prohibitive. Being thus entirely dependent for their supplies of alkali on the Leblanc alkali-makers, it is not perhaps altogether surprising that paper-makers and others should have been contented with the rough and ready method of doing business imposed upon them. If the alkali-maker contracted to supply a consumer with 60 per cent. alkali the latter had no legal ground for complaint so long as the article conformed to the very unscientific criterion known as the alkali test, although, from the nature of this test, the 60 per cent. may have included, and probably did include, a considerable proportion of alkali existing as sulphite, thiosulphate, &c. Of these impurities the aluminate is, as we shall demonstrate, positively harmful, as are also such neutral salts as chloride and sulphate; those salts, on the other hand, which are compounds of soda with weak non-metallic acids, are objectionable rather, because, with a less hydrolytic efficiency than the equivalent of soda *uncombined*, they increase the percentage of Na_2O as returned on the alkali test. We may preface our experimental proofs of these statements by one or two theoretical considerations.

The primary action of caustic soda in resolving raw fibrous materials cannot be more simply or comprehensively expressed than by the term hydrolysis. Hydrolysis belongs to the class of decompositions known as catalytic; the decomposing reagents, whether alkali or acid, undergoing themselves no change in the process. The activity of caustic soda is the property of the soluble base *per se*, or, as we may say, a simple function of the alkalinity of its solutions. Acid radicles, therefore, weaken the activity of the soda with which they are combined, and in proportion to their acidity. The value of carbonate, silicate, sulphate, thiosulphate, and such salts of soda, is therefore less than that of the soda which they contain.

The secondary action of the alkali is that of combining with the products of resolution of the fibre substance and of holding them in solution. Whatsoever, therefore, diminishes the solubility of such compounds is an impediment to the process. This consideration affords a sufficient proof of the objectionable influence of such salts as sulphate and chloride; and when we remember that the colloid hydrates, and notably alumina, are precisely those agents which are most active in fixing organic colouring matters upon cellulose, we should certainly seek to eliminate them from a process designed to undo such combinations. Of the other saline impurities, *e.g.*, sulphite, thiosulphate, and carbonate, we admit from this point of view a certain value, but where the hydrolysis is dominated by caustic soda they can have no other value than that of the soda which they contain.

In a recent paper by Scheurer on the alkaline treatment of cotton textiles in the bleaching process (Bull. Soc. Ind. Mulh. 1888, 399; this Journal, 1888, 841—843), this author contends that the efficiency of the hydrolysis attains a maximum with an admixture of carbonate with the caustic in the proportion of 1 to 3. This paper contains critical references to the Mather keir and the caustic alkali process which it was designed to bring under control. Having been connected with this process since its origin, we take this opportunity of joining issue with Scheurer, on the basis of the experience which has been accumulated, and from which we have concluded that the maximum efficiency is attained with the purest possible solutions of caustic soda. It may also be noted as a digression that to secure

the "bottom" bleach, which is simply the purest possible cellulose, a preliminary treatment of the raw cotton with a dilute acid is necessary, the immediate effect of which we can only regard as the removal of the looser basic impurities. The elimination of these having an important effect on the character of the bleach, it is a fair inference that conversely the presence of bases other than soda have a prejudicial effect upon all similar boiling processes. Returning to the question of the relative efficiency of sodium carbonate, which may be taken as the type of salts of soda with weak acids and caustic soda, we have to introduce the results of experiments upon the "pulping" of the vegetable fibres. We will content ourselves with the more important of these, which were results obtained on the large scale. At a paper mill where esparto was treated, very imperfect boilings were being turned out, notwithstanding that the "alkali" employed was sufficient, as also the other conditions. On examining the liquors employed we found them very imperfectly causticised. On remedying this detail not only were perfect results obtained with quantities of liquor as heretofore, but the proportion of liquor to esparto was considerably reduced, without prejudicing the quality of the pulp.

The relative efficiency of pure and impure (commercial 60 per cent.) caustic soda we tested in the laboratory by experiments also upon esparto. Equivalent quantities of the two reagents were employed under normal and exactly equal conditions. The pulp obtained from the experiment with the pure soda was found to contain 88 per cent. cellulose, that from the 60 per cent. caustic only 77 per cent. cellulose. The external character of the pulps and their behaviour on bleaching corresponded with the difference thus proved in favour of the former.

The effect of the impurity of neutral salts was investigated separately by boilings of esparto with uniform quantities of pure caustic soda, with and without the addition of sodium chloride and sulphate. The addition of these salts caused a considerable deterioration in the quality of the resulting pulp.

We may now sum up our discussion of this branch of the subject with the general conclusion that in all cases where caustic soda is used in the arts as a hydrolytic agent, the maximum of chemical work is obtained *ceteris paribus* with the minimum of impurity in the reagent.

Not only is 60 per cent. caustic inferior from the point of view of chemical action, but also from the point of view of recovery. To prove this point a number of experiments were carried out with pure caustic alone, and with known quantities of impurities. In each case equal weights of alkali were taken, and with the solution known weights of esparto were boiled. The liquors and washing were then evaporated to dryness and incinerated, and the alkali recovered was determined in the ash. The results are as follows:—

	Percentage Na ₂ O recovered.
* Pure caustic	96·3
† 60 per cent. cream caustic	93·4

* The fact that only 96·3 per cent. of alkali is recovered when pure caustic is used is due to the action of the mineral constituents of the esparto.

† This particular sample of caustic soda gave the following analytical numbers:—

NaOH	71·08
Na ₂ CO ₃	8·22
NaCl	8·17
Na ₂ SO ₄	2·38
Na ₂ SiO ₃	3·34
SiO ₂	0·20
Al ₂ O ₃	2·78
Fe ₂ O ₃	0·18

This difference in the amount of soda recovered we believe to be due chiefly to the presence of alumina, which, on ignition with the ash renders a certain quantity of soda insoluble, probably forming with it a kind of glass.

By increasing the relative proportion of alumina, an even greater loss of soda can be effected. Thus 20 grms. of esparto were boiled with 4 grms. of Na₂O and 1·0 gm. of dissolved alumina. The amount of alkali recovered from the ash was only 20 per cent., as against 96 when soda alone was used.

In order to avoid any possible sources of error in these experiments, such, for example, as loss of soda from imperfect washing, a number of trials were made by boiling small quantities of esparto in a platinum dish, and finally evaporating to dryness and igniting. The alkali recovered was estimated by titrating the solution of the residual ash. The results confirmed our observations regarding the loss of alkali if alumina be present.

The importance of these facts to the paper-maker must be obvious to all.

Of the minor disadvantages of caustic of low strength there remain to be noted (1.) the effect of the saline impurity on the consumption of fuel in the evaporation for recovery. The necessary result of their presence in solution is to raise the temperature, while they lower the rapidity of evaporation. Without attempting to express this result in terms of increased consumption of fuel, we may merely note that it is an item of increased expense in this direction. (2.) Those which are common to all impure products, viz., the increased expense of carriage and handling per unit.

It would, of course, be satisfactory to contrast the results obtainable with 60 per cent., 70 per cent., and the magnificent 77 per cent. caustic recently introduced to commerce, in actual numbers, but we will not attempt more than a comparison based upon the more purely chemical factors which we have elucidated.

Assuming the caustic soda, of which the analysis is cited above, to be bought at the same price, *pro rata*, as the pure product, we will show the approximate percentage discount of value deducible from our experimental results.

The sample would show by the ordinary alkali test about 61·66 per cent. of alkali; as a matter of fact it contained only 60·72, the difference being 0·84 per cent. We may safely assume that carbonate of soda possesses only one-half the chemical activity of sodium hydrate; for this we must make a further deduction of 2·40 per cent. Then we have, in addition, the retarding action of 8·47 of chloride, 2·38 per cent. of sulphate, 3·34 per cent. of sulphite, and 2·78 per cent. of alumina. For the whole of these impurities we may safely assume that an increased quantity would be necessary, equal to, say, 5·0 per cent. of alkali.

Although it is very difficult to quantify this retarding action, we know from practical experience that our assumptions are, if anything, below the mark.

Then we have further the loss of alkali during recovery. Taking the loss as 2·9 per cent. on 93·4, this amounts to 1·8 per cent. on 60·72. Putting these figures together thus, we arrive at the following total:—

	Per Cent. Alkali.
Error due to alkali test	0·84
Loss due to imperfect action of sodium carbonate	2·40
Loss due to retarding action of impurities	5·00
Loss of alkali in recovery	1·80
	<hr/> 10·04

That is to say, the caustic in question has only about 85 per cent. of the value assigned to it by the alkali test. Purer products would, of course, show a higher percentage chemical value in proportion to the approximation to purity. But while we freely admit all the mitigating considerations which can be advanced, we affirm, in conclusion, that as we are now in possession of pure forms of alkali, and as these are demonstrated to be more efficient per unit than the impure products, the continued use of the latter can only be defended on the grounds of particular convenience.

CLARKE'S SOAP TEST.

BY FRANK L. TEED, D.S.C. [LOND.], F.I.C., F.C.S.

WHEN a standard soap solution is run into a solution of a calcium salt till a lather is formed, as for instance in determining hardness in water, it is commonly taken for granted that each equivalent of lime destroys an equivalent of soap.

Put in an equational form in the case of calcium sulphate and sodium oleate—

I find that an equivalent of lime requires $1\frac{1}{2}$ equivalents of soap, or CaSO_4 requires $2\frac{1}{2} \text{NaC}_{18}\text{H}_{35}\text{O}_2$.

In the case of magnesium salts the reading is rather more obscure, but an equivalent of magnesia requires rather more soap.

As the mean of many experiments, I find that an equivalent of magnesia requires $1\frac{1}{2}$ equivalents of soap, or MgSO_4 requires $3 \text{NaC}_{18}\text{H}_{35}\text{O}_2$.

I obtained these results both with oleic acid and with the solid fatty acids (commercial stearic acid).

I was acquainted with the above facts at the time that Mr. Allen's recent paper on Clarke's soap test appeared in this Journal, but I was working at the subject with a totally different object, which I have for the present been obliged to relinquish.

Mr. Wanklyn's statement in his "Water Analysis," that magnesium requires $1\frac{1}{2}$ times as much soap as calcium is well known to be incorrect, but it is probably based on the observation that magnesium requires $1\frac{1}{2}$ times as much soap as theory indicates, coupled with the erroneous assumption that calcium requires only its theoretical quantity.

It is a pleasing thing for soap consumers to find that a grain of chalk or magnesia in a water supply destroys $1\frac{1}{2}$ or $1\frac{1}{2}$ times as much soap respectively as has been hitherto thought.

NOTE OF CORRECTION RESPECTING "SALUFER."

BY C. T. KINGZETT, F.I.C., F.C.S.

IN my paper on the comparative antiseptic values of various chemical substances which was printed in the Society's Journal for November 30th, 1888, I made reference to "Salufer," and described some comparative tests which led me to the conclusion that a saturated aqueous solution of that substance has an antiseptic value ranking about equal with that of 5 per cent. solutions of sulphate of aluminium and the chlorides of lead and tin. This, I think, appears clearly enough from the context; but in summing up my results I used the following expression:—"Respecting 'Salufer,' it is seen to

rank about equally with 5 per cent. solutions of sulphate of aluminium and the chlorides of lead and tin."

Mr. William Thomson having taken friendly exception to this statement, I shall be glad to be allowed to state that I did not intend to compare "Salufer"—the pure substance—as an antiseptic with these solutions, but only to indicate the antiseptic value of a saturated solution of "Salufer" in water. "Salufer" is, I understand, soluble in water to the extent of only 0.61 per cent.

Hon. Local Sec. and Treasurer:

W. P. Thompson, 6, Lord Street, Liverpool.

Notices of Papers and Communications for the Meetings to be sent to the Local Secretary.

Meeting held Wednesday, 2nd April 1889, at
University College, Brownlow Street.

MR. A. NORMAN TATE IN THE CHAIR.

THE CHAIRMAN, in opening the proceedings, said that Dr. Hurter was prevented by a domestic bereavement from taking the chair that evening. He hoped that the meeting would offer him their cordial sympathy in his affliction, and express their deep regret for the cause which had prevented his presence among them.

A vote of sympathy was passed unanimously.

The Chairman also called the attention of members to new proposals in connexion with the Elementary Education Act, and advised their perusal with a view to see how far they might be of service to technical education in chemistry.

THE APPLICATION OF ELECTROLYSIS TO QUANTITATIVE ANALYSIS.

BY CHARLES A. KOHN, B.S.C., PH.D., AND J. WOODGATE.

As a labour-saving appliance in quantitative analysis electrolysis needs little recommendation; the electric current does a large share of the work of the analyst and it reduces the amount of manipulation necessary, whilst the electrolysis itself is a simple operation requiring little manipulative skill.

Luckow's method for the determination of copper has come into general use and nickel and cobalt are at times determined electrolytically, but beyond this the various methods which have been suggested

from time to time have been regarded rather as scientific curiosities than as methods which can well bear comparison with the ordinary gravimetric and volumetric determinations. It is in the hope of drawing the attention of chemists to the advantages offered by the methods to be described that we bring this account of our experience with the same before the Society.

Silver, copper, bismuth, mercury, platinum, and palladium can be quantitatively determined as the metal by electrolysis, in a solution of a salt acidified by either nitric or sulphuric acid, whilst thallium, cadmium, tin, antimony, gold, iron, cobalt, nickel, and zinc are only completely separated from solutions of double salts with sodium, potassium, or ammonium.

The following table contains a summary of the most important methods proposed:—

TABLE OF METALS which can be DETERMINED QUANTITATIVELY by MEANS OF ELECTROLYSIS.

		Metals precipitated as such from—	Metals separated as Oxide at Anode from—
I.	Nitric acid or sulphuric acid solution.	Ag. ¹ Cu ² Cd ³ Bi ³ Hg ¹ Pt ¹ Pd. ¹ Zn. ⁴	Tl ⁵ (as Tl ₂ O ₃). Pb ¹ (as PbO ₂). Mn ¹ (as MnO ₂).
II.	Solution of double ammonium oxalate.	TL. ⁵ Cu ¹ Cd ³ Bi ¹ Sn ¹ Pt ¹ Pd. ¹ Fe ¹ Co ¹ Ni ¹ Zn. ¹	Bi ¹ (remains in solution as Bi(OH) ₃). Al ¹ (as Al(OH) ₃). Mn ¹ (as MnO ₂). Cr ¹ (remains in solution as ammonium chromate ⁶). V ¹ (remains dissolved).

APPENDIX.

Cadmium is precipitated as metal from a solution of the double sodium acetate acidified with acetic acid (Smith, Ber. 11, 2048); or from a solution of the double sodium tartrate acidified with tartaric acid (Smith and Kierr, Amer. Chem. J. 8, 204; and Ber. 19, 708).

Zinc is precipitated as metal from a solution of the double sodium acetate acidified with citric acid (Parodi and Mascenzini, Zeits. Anal. Chem. 16, 61); also Lucknow, Jahresber. der. Chem. 1865, 680; and also from a solution of the double ammonium acetate acidified with acetic acid (Riche).

Uranium is separated at the cathode as Ur(OH)₄ from a solution of the double sodium or potassium acetate (E. F. Smith, Ber. 13, 751).

The majority of these methods are due to Prof. A. Classen, of Aachen and he has embodied the results of his work, which dates from 1881, in his book, "Quantitative Chemische Analyse durch Electrolyse,"* which has already entered its second edition in Germany, and a translation of which, by Prof. Herrick, has been published in New York.† It is mainly these methods, which deserve much more consideration than they have hitherto received in this country, both in technical laboratories and in teaching institutions, with which this paper deals.

I.—DESCRIPTION OF APPARATUS REQUIRED.

The Current.—For most of the determinations a current is required giving 10–15 cc. of electrolytic gas per minute (10·436 cc. of electrolytic gas at 0° and 760 mm. = 1 ampère). For this purpose a battery of three Bunsen elements (1 pint size), connected in series, was found convenient; by substituting the nitric acid in the inner cell by a mixture of potassium bichromate and sulphuric acid (10 parts of a saturated solution of potassium bichromate to 1 part of sulphuric acid (conc.)) a current of about equal strength is obtained, which keeps sufficiently constant for 10–12 hours. For weaker currents Daniell or Meidinger cells are the best.

Secondary cells are decidedly preferable to the ordinary voltaic elements, both on account of the regularity of the current obtained and of the trouble saved in recharging. We employed a set of 20 accumulators, each containing five positive and six negative plates, 10 in. long, by 9½ in. high, and which could be charged to 15 to 20 ampères and discharged up to 22 ampères. The E.M.F. of each cell was a little above 2 volts; the internal resistance of course very small and the capacity about 200 ampère-hours when used for the electrolytic determinations. Three such cells connected in series yield a current of 10–12 cc. electrolytic gas per minute with a voltameter and one determination in circuit and an addition of two cells is necessary for each extra solution placed in the circuit. In order to keep the cells fully charged the specific gravity was kept up to 1·200, and not allowed to run down below 1·175 before recharging. The charging was effected by a Mather and Platt No. 2 "Manchester" dynamo (shunt wound), run by a gas engine.

With five cells connected in series and two determinations in circuit at a time 35–40 analyses can be made without having to recharge the cells.

Measurement of the Current.—A Bunsen voltameter filled with sulphuric acid of sp. gr. 1·22, is sufficiently accurate for this purpose, the current being expressed in cc. of electrolytic gas per minute or hour, although a galvanometer has the twofold advantage of being more exact and of introducing

* Published by Julius Springer, Berlin. Price 5s.

† Published by John Wiley and Sons, New York. Price 10s.

less resistance into the circuit. Classen recommends a modified form of Bunsen's voltameter (this Journal, 1888, 401).

Resistance.—In order to regulate the strength of the current a handy form of resistance is needed. Liquid resistances, such as zinc electrodes in a solution of zinc sulphate, or platinum electrodes in dilute acid, are unreliable owing to polarisation taking place too readily, since it is necessary to bring the two electrodes very close together in order to reduce the current by 2 to 3 cc. per minute, the amount mostly required. This is conveniently effected by means of small coils of German silver wire, the resistance introduced by a known length of the same having previously been ascertained for the current and circuit in use. Resistances corresponding to 1, 2, 3, &c. cc. of electrolytic gas per minute, with a current of 10 to 12 cc., were made in this way and found to work very satisfactorily. Finally a rheostat best with mercury connexions, as suggested by Classen, can be employed.

Method of Analysis.—The electrolysis is preferably carried out in a platinum dish of 150–200 cc. capacity, the positive electrode being a piece of platinum foil about 1 in. diameter attached to a thick platinum wire. It is advisable to punch a few holes in the foil in order to prevent the spurring which ensues when a big bubble of gas collects below its surface and then bursts. A nickel dish

lined with platinum was found inefficient for this work, the connexion between the two metals not being sufficiently good. The dish should be covered during the electrolysis; a watch-glass with a hole in the centre answers the purpose if the determination is done in the cold, but if a hot solution is electrolysed, a funnel (the tube of which has been cut off short and widened, and held by a small spring clamp, as shown in the figure) is preferable. The sides of the funnel can easily be kept moist, and thus prevent any spurtings drying on the surface before they can be washed off. For heating the dish a Bunsen burner, the tube of which has been screwed off and with a rose placed over the base, does very well. In carrying out a determination the precipitated metal is washed 2–3 times with water, then twice with absolute alcohol, and dried in the steam bath. The positive electrode should be about 1 in. from the bottom of the dish. It is well to mark the relative positions for the dish and positive electrode on the stand employed.

The arrangement of the apparatus is shown in the following diagram, two determinations being placed in the same circuit. A binding screw is fixed on to the back of the support for the positive electrode, which latter is insulated from the metallic portions of the stand by a piece of glass rod (*a*). The connexion with the dish can either be made on the ring supporting the dish (as shown in figure), or else by means of a binding screw attached to the same.

To protect the metallic connexions from the action of acids they require varnishing; a mixture of lamp-black and copal answers well.

II. DETERMINATIONS.

Antimony.—Antimony is completely precipitated in the metallic form from a solution of its sulphate, obtained by dissolving the sulphide in a concentrated solution of sodium or potassium sulphide of specific gravity (about) 1.22 free from polysulphides. To carry out the determination the precipitated sulphide is dissolved in the solution of the alkaline sulphide, filtered from any separated sulphur, and in case the solution is coloured yellow by the presence of polysulphides, oxidised by gentle warming with a solution of hydrogen peroxide until the solution is colourless. This oxidation is best effected in a porcelain dish and the resulting solution filtered from any sulphide of iron introduced by the reagents

into the previously weighed platinum dish in which the electrolysis is to be made. This is then connected with the negative pole of the battery and the current completed at the voltameter. A current of 1.5 to 2.0 cc. of electrolytic gas per minute is required for the reduction (two Bunsen cells with resistance) which is done in the cold and best allowed to proceed over night. The deposited metal is of a dark grey colour and adheres well to the dish; it is very hygroscopic and increases rapidly in weight during the weighing. It is therefore necessary to check the first weighing by a second drying in the steam-bath and weighing again. Up to 0.2 grm., antimony can be precipitated by the above current in 10–12 hours.

Tin.—Tin is not precipitated from a solution of its sulphide in concentrated sodium or potassium sulphide solution, and advantage is taken of this fact to separate it from antimony. The ammonium sulpho-salt of tin, however, is decomposed with separation of the metal at the cathode. The

sulphide of tin dissolved in ammonium sulphide (free from ammonia) is electrolysed in the cold by a current giving 10 cc.* (three Bunsen cells). Sulphur separates during the electrolysis, which sticks to the deposited metal and has to be carefully rubbed off with the finger whilst the surface is moist after washing with alcohol; this, however, can be successfully accomplished, but the nauseous odour evolved during the reaction (H_2S , SO_2 , &c.), renders the method objectionable.

It is better to precipitate tin from a solution of its double ammonium oxalate when the metal is obtained as a silver white deposit which sticks well to the dish. The electrolysis is effected in the hot solution with a current of 10 cc., and takes five to six hours. Since tin is mostly obtained in analysis in the form of sulphide, this must first be oxidised, best by means of hydrogen peroxide (Classen. This Journal, 1889, 137), and the resulting stannic hydrate dissolved in oxalic acid, the acid neutralised by ammonia and the hot solution electrolysed after the addition of 3–4 grms. of ammonium oxalate.†

The majority of Classen's electrolytic methods depend upon the decomposition of a double oxalate of a heavy metal with that of ammonium, as in the case of tin. It may therefore be of interest to point out the decomposition which takes place. A solution of ammonium oxalate is decomposed as follows by the electric current:—

(1.) *Primary decomposition.*

(2.) *Secondary decomposition.*

At Cathode. $2\text{NH}_3 + 2\text{H}_2\text{O} = 2\text{NH}_4\text{OH} + \text{H}_2$.
The ammonia thus formed combines with the CO_2 liberated at the anode with the formation of ammonium bicarbonate—

The decomposition of the double oxalates of Sn, Fe, &c., with ammonium oxalate, takes place along similar lines.

The (NH_4) forms ammonium bicarbonate as above. Whether the tin is deposited directly or indirectly it is difficult to say, but the ease with which many metals can be separated from double salts of the alkalis in this way points to the indirect separation as the more probable.

Separation of Antimony and Tin.—The precipitate containing the mixed sulphides is dissolved in sodium or potassium sulphide, and oxidised with hydrogen peroxide as above. One gram. of sodium hydrate (in solution) is then added, and the antimony deposited under the conditions already mentioned. In dissolving the sulphides use as little potassium or sodium sulphide solution as possible, and restrict the quantity of wash water in the filtrations as far as is compatible with accuracy in order to save having to concentrate the solution before electrolysis, a process which has to be conducted very carefully and one which involves a considerable waste of time. After the

deposition of the antimony, filter the resulting solution from sulphur and treat it with dilute acid to separate the sulphide of tin, which can then be either filtered off and weighed finally as SnO_2 , or else determined electrolytically as described above.

This method yields good results; it requires careful manipulation, as do all methods for the separation of these two metals. The time necessary for the separation is comparatively short, since the antimony is precipitated over night and the tin in the course of the following day. Should arsenic be also present, the mixed sulphides are dissolved by treatment with potassium chlorate and hydrochloric acid and the arsenic removed by Fischer's distillation method (this Journal, 1887, 353); the residue contains the antimony and tin which are precipitated by sulphuretted hydrogen and then separated as above.

The following determinations were made under the above conditions, the metals being first precipitated as sulphides from the solutions of their salts:—

Iron.—Classen's method yields excellent results in the case of iron. The solution should be free from nitrates and any excess of free acid (except sulphuric acid, which may be neutralised by ammonia), must be removed by evaporation; the resulting iron in the form of chloride or sulphate is first treated with neutral potassium oxalate in sufficient quantity to dissolve the precipitate of iron oxalate first formed (i.e., to form the double salt), and then 5 grms. of ammonium oxalate added for every 0.1 gm. of Fe. The warm solution is electrolysed with a current of 10–12 cc. The metal is obtained as a compact steel grey deposit; it sticks well to the dish and does not oxidise appreciably on exposure—a deposit of 0.2 gm.—Fe only increasing 1 mgrm. in weight after 17 hours' exposure to the air. Complete precipitation is tested by potassium ferrocyanide, a little of the solution in the dish being withdrawn by means of a capillary tube. 0.1 gm. of metal can be precipitated in 2½ hours from a ferric salt; ferrous salts are decomposed more quickly. The deposition can also be effected in the cold, but it takes more than twice the time.

Separation of Iron and Manganese.—Solutions of manganese salts are decomposed by the electric current with the separation of manganese dioxide (MnO_2) at the positive electrode. This decomposition takes place in a solution of the sulphate acidified with sulphuric acid, in a solution of the double ammonium sulphate, or in one of the double ammonium or potassium oxalate. In presence of ammonium salts the separation is incomplete. The result then of electrolysis of a solution of an iron salt under the conditions described above in presence of

* Where not otherwise indicated cc. refer to cc. of electrolytic gas per minute.

† The best way to add the ammonium oxalate is to dissolve the requisite quantity in hot water and filter the hot solution into the platinum dish.

manganese is that the former is deposited as metal at the cathode, whilst the latter separates partially as MnO_2 , a portion of which adheres to the positive electrode, a portion floating about in the solution. To effect the separation quantitatively, electrolyse the hot solution containing the mixed salts, after the addition of potassium and ammonium oxalate as above with a current of 10–12 cc. The presence of manganese tends to reduce the rate at which the iron is precipitated, but it in no way affects its completeness, or the tenacity with which the metal adheres to the dish. The contents of the dish are poured off as soon as the whole of the iron is precipitated and the metal washed, dried, and weighed. The manganese dioxide sticking to the positive electrode as well as that suspended in the solution is dissolved in hydrochloric acid, and the manganese precipitated by means of bromine and ammonia and weighed as Mn_2O_3 as usual.

Beyond trying this method with mixtures of the salts we have also used it in the analysis of spathic iron ore, and in the separation of iron and manganese in a sample of metallic iron, in all cases with satisfactory results. In the former instance the ore, which contained SiO_2 , FeO , MnO , CaO , MgO , and CO_2 , was dissolved in hydrochloric acid; the silica removed as usual, and the filtrate treated with potassium and ammonium oxalates. Calcium, together with some manganese is precipitated; the filtrate contains the iron, the rest of the manganese, and the magnesium; this was then electrolysed and the manganese precipitated in the filtrate by bromine and ammonia. This precipitate, together with that originally obtained by the addition of the oxalates, must be ignited to decompose the oxalates, dissolved in hydrochloric acid, and the resulting solution added to the filtrate from the manganese precipitate; the separation of manganese, calcium, and magnesium is then conducted in the usual way. The presence of calcium considerably complicates the separation of the iron and manganese, but in its absence, as in the case of metallic iron, spiegeleisen and the like, the advantages of the method are more apparent since the complete separation of the two can be effected in the solution of the metal after the removal of the carbon, silicon, &c.

Separation of Iron and Aluminium.—Solutions of aluminium salts, when treated with an excess of ammonium oxalate and electrolysed, are decomposed with the separation of the hydrated oxide ($Al(OH)_3$) at the anode, but this separation only takes place after the current has been passed for a long time and the hydrate does not stick well to the electrode. To separate iron and aluminium, the hot solution containing the mixed salts, after the addition of potassium and ammonium oxalates, is electrolysed with a current of 10–12 cc.; as soon as all the iron is deposited, decant the solution, wash, dry, and weigh the iron, and determine the aluminium as hydrate by precipitation with ammonia in the usual way, after first boiling the solution so as to decompose the ammonium and potassium bicarbonates formed.

Should it be necessary to pass the current so long as to separate a portion of the aluminium as hydrate, this is readily brought into solution again by the addition of a few drops of hydrochloric acid.

The advantage of this method over the ordinary gravimetric method for the separation of these two metals is evident; no double precipitation is necessary, and the presence of fixed alkalis is (save for the small amount of potassium carbonate present) entirely avoided.

Separation of Iron and Chromium.—Chromium salts are oxidised by the current in presence of

ammonium oxalate to ammonium chromate. In the separation of iron and chromium the solution is treated with potassium and ammonium oxalates and electrolysed as above; as soon as the iron is completely deposited, decant the solution at once, wash and weigh the iron, otherwise the alkaline chromate formed will be found to oxidise the iron and thus bring the results too high. Further, by the prolonged heating of the ammonium chromate solution, the hydrate of the oxide Cr_2O_3 separates in yellowish brown flocks, which adhere very tenaciously to the surface of the metal. Since the presence of oxalic acid prevents the complete precipitation of chromium by ammonia, the alkaline oxalates added must first be completely decomposed. This takes longer than is necessary for the precipitation of the iron, and in order to avoid the sources of error above referred to the solution, after the separation of the iron, is transferred to a second dish in which the decomposition of the oxalates is completed. A current of 10 cc. suffices to decompose 5 grms. of oxalate in six hours. The chromium can then be precipitated by ammonia after reduction with alcohol and hydrochloric acid and weighed as Cr_2O_3 .

The following results were obtained by the above methods:—

Nickel.—Nickel is precipitated from a solution of the double ammonium oxalate as a silver white deposit which adheres well to the dish. If the nickel is obtained in the form of sulphide in the course of

analysis, this is dissolved in aqua regia, the excess of acid evaporated off, and the nitric acid completely removed by taking up the residue with hydrochloric acid, and again evaporating to dryness. The solution of the chloride is then treated with 4 grms. of ammonium oxalate, and electrolysed hot with a current of 10 cc.; 0.1 gram of nickel is precipitated in two hours.

Fresenius and Bergmann's method consists in treating the solution with an excess of ammonia, and then adding 4--5 grms. of ammonium sulphate. A current of 5 cc. is sufficient (two Bunsen cells). Both methods yield satisfactory results.

We also tried the determination of nickel from a solution of the double potassium cyanide with a view to separate cobalt and nickel by converting the former into the cobaltcyanide, and the latter into the double potassium cyanide, and electrolysing the resulting solution. Nickel can be completely precipitated in this way, but our results up to the present are not sufficiently conclusive to show whether a separation of the two metals by this means is possible or not; and since Dr. G. Krüss has recently thrown doubt upon the elementary nature of these two bodies,* we have discontinued our experiments on this point for the present.

Cobalt.—This metal can be determined similarly to nickel, both in the solution of the double ammonium oxalate and in that of the double ammonium sulphate. The complete precipitation of both cobalt and nickel is best tested for by the red-brown colouration obtained with a solution of potassium sulphocarbonate (K_2CS_3).

The determination of manganese in presence of nickel or of cobalt is carried out as in the case of iron, the manganese separating partially at the anode as MnO_2 , both from the solution of the double ammonium oxalate and also from that of the double ammonium sulphate; in neither case is the separation complete.

Zinc.—Several methods have been proposed for the determination of zinc (*vide* Table). From a solution of the double ammonium oxalate the precipitation is slow, and the metal, which does not adhere very fast to the dish, is obtained in the form of a fine crystalline powder which can easily be rubbed off with the finger. The precipitation should be effected in the cold by a current of 10--12 cc.

after the addition of 4 grms. of ammonium oxalate; if a hot solution be employed, the deposited metal adheres very badly.

If the ammonium double sulphate be electrolysed, the result is similar, the metal showing a like tendency to become detached in the washing. To prepare this latter solution, add ammonia to the solution containing the zinc until the precipitated hydrate is redissolved, and then 5 grms. of ammonium sulphate; electrolyse in the cold with a current of 12--14 cc. In both cases it is best to allow the determination to go on over night; 0.1 to 0.15 gram of metallic zinc can be completely precipitated in 8--10 hours.

The potassium ferrocyanide reaction is not sufficiently delicate to test whether the zinc is all precipitated; at least six hours should be allowed for every 0.1 gram of zinc; the time varies considerably with the smoothness of the surface of the dish. The deposited zinc attacks the platinum of the dish slightly and although the greater portion of the metal is readily dissolved off by dilute acid, a dark brown stain remains which can only be removed after prolonged ignition and treatment with hot acid; for this reason, a layer of metallic iron (or other metal) must first be deposited in order to protect the platinum. A further disadvantage in the electrolytic method for the determination of zinc lies in the fact that at times the metal is deposited in a spongy form; in such cases the precipitate sticks well enough to the dish, but it retains the salts in the solution very tenaciously, and thus leads to high results. From these considerations it is clear that electrolysis offers little attraction as a means for the estimation of zinc; as long as the quantities of the metal are less than 0.1 gram, the methods described give fairly accurate results, but they are far less reliable than the electrolytic methods for the determination of antimony, tin, iron, cobalt, or nickel.

Separation of Zinc and Manganese.—Zinc and manganese are separated as in the case of nickel and manganese but there is always a risk of washing off a little of the precipitated metal with the manganese dioxide, especially if the quantity of zinc exceeds 0.1 gram.

Separation of Zinc and Iron.—Iron in the presence of zinc is precipitated with it at the cathode from a solution of the double oxalates as long as the proportion of Fe to Zn is more than 3:1; if the proportion of zinc is greater, some of it goes back into solution, and ferrie hydrate separates. (Classen. Ber. 17, 2481.)

In determining the two metals in samples of crude zinc, hard spelter, and the like, where the above proportion is exceeded, the following process, which we adopted in an analysis of this nature, works well. The spelter analysed contained lead, iron, and zinc. After removing the lead by means of sulphuric acid, the filtrate is treated with an excess of ammonia, when a precipitate results containing the whole of the iron, and a little of the zinc, the remainder of the latter being in the filtrate. Dissolve the precipitate in acid, and after evaporating off the excess, electrolyse the resulting solution after the addition of potassium and ammonium oxalates. Then dissolve the deposited metals in hydrochloric acid, and titrate the iron with potassium bichromate after reduction with stannous chloride, the quantity of zinc of course being obtained by difference. The filtrate from the precipitated hydrates must be neutralised with oxalic acid (if a precipitate forms add a drop or two of ammonia until it is dissolved) and then electrolysed after the addition of ammonium oxalate; or else 5 grms. of ammonium sulphate are added, and the alkaline solution electrolysed as described.

From solution of double sulphates....	{ 0.0862 Zn	0.0862
	{ 0.1355 Mn ₂ O ₃	..

We have also obtained satisfactory results with mercury and silver, the former being electrolysed in a solution acidified with nitric acid, with a current of 3–4 cc., the latter from the double potassium cyanide, with a current of 1–2 cc. In both cases the deposition is complete, and the deposited metal adheres well to the dish.

The methods described form only a portion of those recommended by Classen, and which have been worked out with satisfactory results in his laboratory, where the arrangements for this electrolytic work are very complete.

In his book already referred to methods will be found for the determination of copper, bismuth, lead, cadmium, thallium, platinum, palladium, and gold, and for the separation of these and of the metals treated of in the paper in part from one another and in part from other metals, chiefly those which are not precipitated in the metallic form from solutions of their double ammonium oxalates (Al, Cr, Mn, Fe); Classen also gives a long series of examples of analyses which can be carried out by these electrolytic methods.

The real value of these methods to the analyst, when compared with the volumetric and gravimetric methods in use, depends greatly on the nature of the work done, but there is little doubt that all chemists will be able to find some of them of decided advantage, and by judiciously combining the same with the ordinary methods employed, a saving both of time and labour should be effected.

DISCUSSION.

The CHAIRMAN said that the author had given the meeting an excellent digest of the various electrolytic operations suggested for use in chemical analysis; but before these processes could be fully relied upon for making quantitative determinations for analytical and technical purposes, they would require further trial and investigation. At the same time the thanks of the meeting were due to Dr. Kohn for bringing the subject before the Society in such a manner as to encourage other members to pursue a subject which might prove of great practical value to analytical and technical chemistry.

Dr. J. CAMPBELL BROWN said that in these days, when electricity was applied either nominally or really to all sorts of purposes, it was satisfactory to find a case in which not merely the name, but the actual current was being applied successfully. The application of electrolysis to analytical purposes was by no means new; and they were all aware of its use, as for instance in the case of Reinsch's arsenic test, and the elegant method of determining copper now more than 20 years old. That being so, it was to him

very surprising that electrolysis had not come into more general use. Possibly analysts had not taken the trouble to teach themselves how to apply it, and he was quite sure that their Society would approve of Dr. Kohn's lucid exposition of the method, and the details which he had given them of his experience both in practice and in teaching the processes. In those cases where the difference between the strength of current necessary to precipitate the whole of one metal without commencing to precipitate the other, was very fine, he would like to ask whether it would really be feasible to attain the exact degree of strength of current so as to make the method applicable? Dr. Kohn had indicated to them a sufficient number of metals which could be neatly, conveniently, and easily determined electrolytically to make it desirable that every analyst should be familiar with the methods. When once the application of electrolysis became common, then its extension to other metals would gradually proceed as they acquired more experience, and as different experimenters exchanged views, and told each other the results of their experience. He hoped that they would have more papers of this kind in their Section, for the application of new methods of analysis would be of peculiar use in their Society. Already there were valuable methods in private use which deserved greater publicity.

Mr. KNIGHT said he could not help feeling that if there were any present, like himself, employed in analytical work, principally metallurgical, they would be thankful to Dr. Kohn for bringing all those useful methods before them. He had heard a good deal from Dr. Kohn which he was sure would be useful to him in the future. The method he was principally interested in was the separation of antimony from tin. Any chemist constantly employed in the separation of these metals would know what a difficulty there was to do this quickly and obtain reliable results. He should like to know whether there was any difficulty in the separation of antimony and tin when the proportion of tin was very much larger than the proportion of antimony, say 95 per cent. tin and 5 per cent. antimony.

Dr. KOHN said that his experiments had been in the opposite direction, in which the antimony was in excess; but that he had no doubt the separation could be made to work equally well in cases in which there was a large excess of tin.

Mr. KNIGHT said that in commerce the general run was to estimate antimony in commercial tin, and if it could be done practically by electrolysis it would be a very great help.

Mr. ALEXANDER WATT asked if the exact strength of the current used could be given in amperes?

Dr. KOHN, in reply, said that he had not tried the method for the separation of antimony and tin in presence of large amounts of tin and very little antimony. The method, as far as he knew it, was one rather for the separation of tin from antimony than of antimony from tin. It was certainly well worth trying under the suggested conditions; the separation was so complete in the cases given, that there was every reason to hope that it would be equally so in presence of a large excess of tin. Dr. Campbell Brown had asked whether it would be easy to regulate the strength of the current in separations. In the first place perhaps he did not point out sufficiently clearly in the paper that the strength of current need only be approximately regulated, *i.e.*, whether they had 10 cc. or 12 cc. of electrolytic gas per minute, or whether sometimes

it went down to 9 cc. or up to 13 cc., did not materially affect the majority of determinations with which he had had to deal. The slower the current the longer the deposition took, and *vice versa*. The separations in most cases did not depend upon the strength of the current; for instance, take the separation of antimony and tin. Tin was not precipitated at all from the solution of its sodium or potassium sulpho-salt, provided the solution was a concentrated one; they could accordingly put on a much stronger current than needed for the precipitation of antimony without precipitating any tin at all. Mr. Watt had asked him to express the strength of the current in amperes; one ampère was equivalent to 10.436 cc. of electrolytic gas per minute. In conclusion he felt very glad that some interest had been excited in these methods which he brought before them, and he trusted that those who had not tried them might be led to do so. They were methods which were not simply to be read of in books, but to be tried and worked out, and it was only by analysts trying the way the method worked in their hands that its real value would become apparent.

The Sixth Meeting of the Session was held in the Societies' Rooms, 207, Bath Street, Glasgow, on Tuesday, 2nd April 1889.

MR. E. C. C. STANFORD IN THE CHAIR.

ON DYEING WITH MIXED COLOURS.

BY EDMUND J. MILLS, D.S.C., F.R.S., AND J. J. HAMILTON.

It has long been a practice with dyers to obtain modifications and changes of shade by employing in the vat two or more colouring matters at the same time. The results of such an admixture are, as might have been expected, far more complicated

than those which attend the process of dyeing with a single colour. The specific action of each tinctorial constituent is modified by each of the others; and the general phenomena—far from always preserving a gradual character—occasionally exhibit what appear to be the abruptest transitions.

It is now known that the process of the dye-vat admit, in many cases, of fairly accurate measurement. We have, therefore, thought it of interest to determine, as exactly as we could, the nature of the transaction which occurs when wool is acted on by two soluble colours conjointly. Reference may be made to a precedent for this investigation in a research by Mills and Smith (*Proc. Roy. Soc. XXIX.*, 181) on the equivalence of nickelous and cobaltous sulphates, as precipitated by weak caustic soda solutions. The conclusions were, that precipitability is proportional to mass of precipitable substance; and that, for an equal weight, nickelous and cobaltous sulphates are equally precipitable: the attraction of the one towards the reagent being inverse to that of the other.

It was by no means easy to select two suitable colours. We first made experiments with a mixture of picric acid and Victoria blue (4 R.). This, when heated to the boil, was capable of dyeing a green colour on white cashmere (tissue). But after cooling and allowing the liquid to stand for some time, the blue in the solution began to settle out and could not be estimated. Several attempts were made to keep the blue from precipitating, but they were unsuccessful. It was evident that picric acid precipitated the blue, and another yellow colouring matter was resorted to.

A solution containing Victoria blue and hydrochloride of berberine (yellow) was heated to a temperature of 94° C., and kept at that point for one hour. No blue separated out during the heating, nor after standing for 48 hours. A similar experiment was then made with a piece of cashmere in the vat, the liquid being kept at about 95° C. The cashmere was dyed blue, and not green. A skein of woollen yarn worked in and out of the vat, after the cashmere had been dyed, was dyed green. The nearly-exhausted vat still dyed cashmere blue.

We next tried the effect of a lower temperature on the deposition of the colours. An experiment was made at 40° C., a piece of cashmere being inserted at that temperature. The cashmere was dyed green. On heating the solution, along with the cashmere, to boiling, the wool was dyed blue on the top of the green. A temperature of 40° C. was therefore selected for the dyeing experiments.

Standard solutions of Victoria blue and berberine hydrochloride were made up. The Victoria blue solution was prepared by dissolving a quantity in cold water, letting it stand overnight, and filtering.

This was diluted with water to about twice its bulk. The amount of substance in this solution was estimated by evaporating 20 cc. of it to dryness, in a vacuum, over sulphuric acid, and weighing the residue. The residue from 20 cc. weighed .139 gm. Each cc. of the solution therefore contained .00695 gm. blue.

The yellow solution was made by dissolving berberine hydrochloride in a large quantity of water and filtering off from some insoluble matter. The chloride in 250 cc. of this solution was precipitated with nitrate of silver. The chloride of silver was filtered, washed, dried, ignited, and weighed. 250 cc. of solution gave a precipitate of .133 gm. argentic chloride, which is equivalent to .3452 gm. hydrochloride of berberine ($C_{20}H_{11}NO_4 \cdot HCl$); so that 1 cc. contained .00138 gm. of colouring matter.

A piece of cashmere was cut into pieces about 38 in. long, and $1\frac{1}{2}$ in. broad. Each piece was by clipping made to weigh 4.94 grms., and was then scoured in a dilute solution of ammonia, washed, and dried in a quiet room. When dry the pieces were folded up and kept in a glass bottle. Care was taken in the subsequent operations never to touch the wool with the hand. The pieces were lifted out of the bottle either with polished iron tongs or with a glass rod.

Distilled water which had been recently boiled and cooled was used in the experiments; and the cashmere, before dyeing, was boiled off for some time in distilled water. Thus the formation of air bubbles on the cloth while dyeing was obviated.

The dye-vat used was a large Bohemian glass beaker, capable of holding $2\frac{3}{4}$ litres of water. The vessel was filled with two litres of water, and at the level of the liquid a mark was made on its side.

Method of making the Experiments.—The beaker was filled to within about 200 cc. of the 2-litre mark, with water heated to about 30° C. The measured quantities of the blue and yellow solutions were then added. The blue was always added first and stirred well into the liquid before adding the yellow. The liquid in the beaker was then made up with water to the 2-litre mark. The mouth of the beaker was covered half over with a glass plate, and a thermometer, graduated to 1° C., was suspended with its bulb in the centre of the liquid. A stirring rod was also inserted in the beaker, which was mounted on an ordinary retort stand, and heated by a small Argand burner. The whole was surrounded by a metal screen so as to avoid draughts.

The liquid was next heated up to 40° C., and when the temperature had been steadily maintained at 40° C. for some time, one of the weighed pieces of wool, which had been boiled off with water, was put in. The liquid was stirred every few minutes, and the wool was dyed in it for an hour and a half and removed.

The liquid was allowed to cool, and made up with a small quantity of water to the 2-litre mark, and a sample was then put into a bottle, labelled with a letter denoting that particular experiment.

After each experiment a blank solution was made up containing the colouring matters in the same proportions as were in the liquid before dyeing. This was also bottled and labelled.

The following table shows the variations of temperature during one experiment:—

TABLE I.

Minutes.	Temp.	Minutes.	Temp.	Minutes.	Temp.
	° C.		° C.		° C.
0	40.0	34	39.8	64	39.9
9	39.9	39	39.8	69	39.9
14	40.0	44	40.1	74	40.0
19	40.1	49	40.2	79	40.3
24	40.1	54	39.9	84	40.2
29	39.9	59	39.7	89	40.0

The weight of the colouring matters present ranged from .01 grm. of blue and .19 grm. of yellow

to .15 grm. of blue and .05 grm. yellow, the total weight of colour being constant, viz., .20 grm.

Estimation of the Colours.—The solutions kept in the bottles were afterwards examined by means of the detached colorimeter described by one of us (Phil. Mag. 1879, I., 437). The method of examination was as follows:—

Take the experiment G, in which case .1 grm. of blue and .1 grm. of yellow were used. The solution in which the wool had been dyed was labelled G, and the solution containing the colours as they were before dyeing was labelled G₁. 100 cc. of G₁ contained .005 grm. blue and .005 grm. of yellow.

100 cc. of each liquid were measured out and run into the two glass cylinders of the colorimeter, and shades were compared. G was found to be a little yellower in shade than G₁. Accordingly, two drops of the standard blue solution were added to G. The shades of G and G₁ were then alike, but they differed in depth, G being much more dilute than G₁. Water was next added to G, until its shade was equal in depth to that of G₁. It was found that 85 cc. of G₁ required to be diluted with 21 cc. of water. 100 cc. of G + 2 drops blue, therefore, contained as much colouring matter

as $\frac{8500}{106} = 80.189$ cc. of G₁. Omitting, for reasons

stated hereafter, the two drops blue, 100 cc. of G contained $(80.189 \times .00005 = .00400945$ grm. blue and $80.189 \times .00005 = .00400945$ grm. of yellow. Two litres of G, therefore, contain .080189 grm. of blue and .080189 of yellow; and, since the quantity of colour originally in two litres was .10 grm. of blue and .10 grm. of yellow, there must have been deposited on the goods .019811 grm. of blue and .019811 grm. of yellow.

On examining all the solutions, it was found that a small quantity of blue had to be added to the liquid in which the wool had been dyed, to bring it up to the same shade as the standard. This quantity, except in only two experiments (one of which was repeated, and in the other, an error was supposed to have been made), never exceeded 3 drops of standard blue solution per 100 cc. of liquid. As there was always a very small quantity of blue deposited on the side of the beaker while dyeing, and as the loose woollen threads of the cashmere were dyed blue, or a much bluer shade than the cloth itself, the small quantities of blue which required to be added were taken as the correction required, and were, therefore, omitted in calculating the amount of blue deposited on the cloth itself. On this understanding, it follows that the proportion of blue to yellow deposited on the goods is the same as that in which they existed in the vat before dyeing. What also points to this conclusion is, that in no case did we require to add yellow to the partially-exhausted liquor in order to bring it to the same shade as the standard.

In some cases it was found that the blue in the blank solution had separated out before measurement. Fresh solutions had, therefore, to be made up. In experiment D, the blue had also separated out from the partially-exhausted liquid, and a fresh trial had to be made. In experiment F, the dye-vat was, by accident, heated to about 50° C., and had to be cooled again. The temperature was also very irregular during the dyeing operation. Here, also, another experiment was made, viz., G. A, which was the first done, and, therefore, as is usual with first experiments, likely to be irregular, was also repeated. The results of experiment C being evidently subject to some large error, were not further considered.

The accompanying table shows the results obtained:—

It will be observed that the *total quantity of colouring matter deposited on the goods is least when the weights of the blue and yellow are equal, and that it becomes greater as the disparity between the weights increases.*

The simplest mathematical treatment of the reaction consists in finding an equation for each of the colours separately. Such equations are of the form—

$$y = a + \frac{\beta x}{1 - \gamma x};$$

γ being the reciprocal (= 5) of the total constant quantity (.2) of colour taken as a reagent; and β , a constants of attraction and other conditions. In particular, the constant a represents the effect of an attraction not directly related to the dyeing process as such. This is indicated by the fractional expression: x corresponds to the weight taken of a specific colour, y to the weight deposited therefrom on the goods.

TABLE III.

COMPARISON between THEORY and EXPERIMENT (BLUE).

$$y = .006978 + \frac{.0885x}{1 - 5x}$$

x .	y calc.	y exp.	x .	y calc.	y exp.

'09	'021460	'018358			

Sum of the differences = - .000715. Probable error on a single observation = .001457.

TABLE IV.

COMPARISON between THEORY and EXPERIMENT (YELLOW).

$$y^1 = .016526 + \frac{.0378x^1}{1 - 5x^1}$$

x^1 .	y^1 calc.	y^1 exp.	x^1 .	y^1 calc.	y^1 exp.
'05	'019046	'020970	'12	'027866	'027600
'06	'019766	'022121	'14	'034466	'035614
'07	'020597	'021269	'15	'039206	'040384
'08	'021566	'022761	'16	'046766	'045940
'09	'022711	'022480	'17	'053666	'061973
'10	'024086	'019811	'18	'081566	'081616
'11	'025766	'022438			

Sum of the differences = - .000467. Probable error on a single observation = .0015091.

When $y = y^1$, $x = .09882$ and $x^1 = .10118$, equal weights, therefore, of the two colours are equally precipitated on the goods.

In the two equations, the denominators of the fractions are $1 - 5x$ and $1 - 5x^1$ respectively. Now, $1 - 5x = 5(.2 - x)$, and $.2 - x = x^1$. So that $1 - 5x = 5x^1$, and for the same reason $1 - 5x^1 = 5x$. The two equations may be written—

$$(\text{Blue}) y = .006978 + \frac{.0885x}{5x^1} \left(\text{or } \frac{.0177x}{x^1} \right), \text{ and}$$

$$(\text{Yellow}) y^1 = .016526 + \frac{.0378x^1}{5x} \left(\text{or } \frac{.00756x^1}{x} \right).$$

The conclusions from these equations are, that in the case of dyeing wool with mixed solutions of berberine hydrochloride and Victoria blue (\pm R.), there is, first, a certain small amount of each colour (a) deposited on the goods, irrespective of the

amount of each colour taken, and that the quantity of each colour which is afterwards dyed on to the wool is proportional to its own mass, and inversely proportional to the mass of the other colour.

CURVE showing the relationship between BLUE colouring matter TAKEN and that DEPOSITED, corresponding to the equation $y = \cdot 006978 + \frac{\cdot 0885x}{1-5x}$.

CURVE showing the relationship between YELLOW colouring matter TAKEN and that DEPOSITED, corresponding to the equation $y = \cdot 016526 + \frac{\cdot 0378x}{1-5x}$.

Yellow colouring matter deposited (in grams) is represented along the ordinate. Yellow colour taken is represented along the abscissa (horizontal line).

An interesting relation exists between the constants. It is as follows:—

$$\frac{\alpha^1}{\alpha} = \frac{\cdot 016526}{\cdot 006978} = 2.37, \text{ which is nearly equal to } \frac{\beta}{\beta^1} = \frac{\cdot 0885}{\cdot 0378} = 2.34.$$

The ratio between α and α^1 is the reciprocal of the ratio between β and β^1 .

It is evident, as a practical inference from this investigation, that the least effective proportion in which dyes should be mixed is that of equal weights. On account also of the existence of the inverse junction, a "self-colour" must always be more efficient, and least likely to produce irregular effects in dyeing, than any mixture having the same shade.

DISCUSSION ON MR. ROWAN'S PAPER ON
FLAME (JOURNAL VIII., 179).

MR. W. FOULIS quite agreed with Mr. Rowan as to the importance of this subject, for the fuller our knowledge of the properties of flame the more readily would we solve many of the problems relating to fuel consumption, furnace temperatures, utilisation of gas for light, heat, and power, and many questions of great importance in all kinds of manufactures. He thought some reference might have been made to the experiments of Mr. F. Siemens, especially to those dealing with the temperatures of dissociation. The rate of progression of flame in a combustible mixture was of considerable importance. The method of ascertaining this, described in the paper, required great care to obtain accurate results, and it seemed easier to note the time flame takes to travel through a tube of a given length, say 50 or 100 feet, filled with an explosive mixture. The effect of pressure on the rate of progression had not been determined, so far as he knew, though it was well worth accurate investigation; indeed, the whole subject of the effect of pressure on combustion deserved further study. That it had a considerable effect there could be no doubt; thus compression raises the flame temperature, and a mixture of air and coal gas which, at atmospheric pressure, could scarcely be ignited, would burn rapidly if compressed.

The management of combustion so as to produce the flame best suited for the purpose to be secured needed careful attention. He had considerable experience of this in the first introduction of heating by gas the retorts in the gasworks under his charge. In the first attempt made the gas was introduced in comparatively small jets, and so arranged as to be immediately brought into intimate contact with the heated air. The result was a number of short flames, causing local heating, and melting the brickwork, which was of best quality. The ultimate success of this system of heating depended to a very great degree on the method by which the air and gas were brought together so as to produce lengthened combustion and an equal heat throughout the entire setting. There could be no doubt that many failures of heating furnaces of various kinds had been due to want of attention to the method in which the combustion had been accomplished.

On the question of the temperature of dissociation he was inclined to agree with the opinion expressed by Mr. Siemens in a paper contributed to the London Section of this Society, that many of the results attributed to dissociation were in reality due to imperfect combustion, one of the most frequent causes of which was surface interference with the free motion of the gases during combustion. In burning gas for purposes of illumination we knew how important it was that there should be no interference with the free motion of the gases—no cross currents, or indeed currents of any kind—and that the best results were obtained when the gas was allowed to issue from the burner into a still atmosphere at so slow a rate that it might be said to be practically at rest.

The experiments on dissociation referred to in Mr. Rowan's paper were made with very small quantities of gas, and the gases were exploded in narrow tubes, the surfaces of which were cold. What influence these cold surfaces would have in checking combustion was undetermined, but no one accustomed to experiment on the combustion of gases would doubt that it must have been very considerable, and, from the manner in which the

experiments were made, imperfect combustion would have all the appearance of dissociation. One circumstance of importance connected with the dissociation of gases at any known flame temperature was the fact that all flames when burning freely without contact shorten as their temperature is increased. If even very partial dissociation took place, there would necessarily be a lengthening of the flame. A very good illustration of this shortening is seen in the case of regenerative gas burners, in some of which very high flame temperatures are reached. When the burner is cold and the flame necessarily supplied with cold air, the flame is long and smoky, but as the temperature increases by the heating of the air supply, the flame shortens, and in the best regenerative burners the gas burns with a comparatively short flame of high temperature and great brilliancy. When a mixture of air and gas in the exact proportions required for combustion is burned in a closed chamber or otherwise protected from the atmosphere, the flame shortens so much that combustion seems to take place without any visible flame. [Mr. Foulis illustrated this by a striking experiment.]

With regard to the luminosity of flame, he thought he might safely say that the theory held by all engaged in the manufacture of gas for illuminating purposes is that the luminosity is due to free carbon in the flame. This theory was well described by Mr. F. Siemens in a paper "On Combustion," read to the Iron and Steel Institute. It was this theory which guided the work of those who have endeavoured to improve the illuminating power of coal gas. We know that this free carbon can be produced from a coal-gas flame, and we also know that the best photometric results are obtained when the flame is just on the point of smoking, that is to say, when the separation of the carbon is at a maximum consistent with complete combustion. The unconsumed gas in the interior of an ordinary coal-gas flame is subjected to a high temperature, and hydrocarbon gases at high temperatures part with a certain proportion of their carbon, and therefore it is that thick flames are as a rule smoky flames. The high results given by regenerative burners (in many of which the light given per cubic foot of gas consumed is double, and in some cases considerably more than double that obtained from ordinary burners) is not entirely due to the heating of the air supply, but in a great measure to the more intense combustion permitting the use of thick flames, in the interior of which there is greater room for the separation of carbon. It would probably be too much to say that there can be no luminosity without solid particles, but he thought it might safely be said that all artificial illumination is derived from incandescent solid matter. This was quite apart from the question as to whether and why gases which burn in ordinary circumstances with non-luminous flame become luminous when consumed under high pressure. There can be no doubt that pressure has a considerable effect on the luminosity of flames.

MR. ROWAN said that he would reply to Mr. Foulis's remarks in so far as they were controversial.

He had not said anything about specific applications of flame because he did not wish to add to the length of the paper in that way. He had aimed at presenting a general view of the information which was available on such points as the nature, temperature, propagation and luminosity of flame, because he believed that the more the understanding of these points spread the more easy it would become for special applications of flame to be made in an intelligent manner.

He was acquainted with the views expressed by Mr. Frederick Siemens in his various papers to which Mr. Foulis had referred, but he had not quoted Mr. F. Siemens because he did not think his views well founded. In this he referred specially to his views of the nature of flame and on "heating by radiation only," as expressed by Mr. Siemens. Mr. Siemens' remarks on the influence of surfaces in limiting dissociation temperatures were, however, undoubtedly deserving of careful consideration.

The "heating by radiation only" theory required, according to Mr. F. Siemens, the adoption of the so-called "electrical" theory of flame in order to its being properly estimated; whilst according to Dr. Armstrong the view of Mr. Siemens depended entirely on the acceptance of another theory of the nature of flame. This was not very encouraging, but it was more satisfactory to find Mr. F. Siemens in his latest papers practically giving up the "radiation only" view and preferring to describe his idea as "heating with free development of flame," which commended itself much more readily to common sense.

The method of estimating the rate of flame propagation suggested by Mr. Foulis seemed to him to be open to objection, on the score that the disturbing element of contact between the flame and the sides of the tube would be introduced, and this would interfere with the accuracy of any such method of determination.

It is true that very little is known as to the rates of ignition under increasing pressures, and this he had alluded to in the paper. At the same time it might safely be concluded, from all that was known, that increase of pressure tends to increase the temperature and also the luminosity of the flame. He did not know of any deviation from this rule.

As to the question of dissociation, he did not think anything could be proved from the mere shortening of hot flames in the absence of analyses of the escaping products to determine the amount of combustible gas escaping. The shortening of most flames, even on a large scale, as in gas furnaces, by increase of temperature, is a fact, but where surface interference is not present this does not argue dissociation, but rather more rapidly completed combustion.

On the subject of luminosity he thought the theory referred to by Mr. Foulis, and described by Mr. Siemens, would not stand the test of severe criticism. In the first place, although it was quite possible that the flame of hydrocarbon gas contained solid particles, yet it had not yet been *proved* that these particles influenced the degree of luminosity, or even that they were solid carbon. The black deposit produced by presenting a cold surface to the flame of hydrocarbon gas was not carbon, but was a hydrocarbon compound. Granting that smoke consisted mainly of solid carbon particles, this would not help the view that luminosity depended on the presence of solid particles, for a smoky flame was not luminous.

The experiments of Soret and Burch, quoted in the paper, seemed to show that some kind of solid particles may exist in hydrocarbon flames, but although it may perhaps be *assumed* that the light in these experiments was reflected from solid particles, yet it remains to be *proved* that there is any relation between the presence of these particles and the luminosity of the flames.

The theory referred to by Mr. Foulis was ingenious, because it was a fact that hydrocarbon gas on being heated prior to combustion deposited part of its carbon. But whilst that result demanded the application of some external heat, this theory required that such preliminary heating should take place in

the flame itself. Now the blue part of the flame was the only part which contained unconsumed gas, where consequently this preliminary heating should take place. But the blue portion of the flame was not hot. The hot part was the luminous part, where, according to this view, the solid particles previously separated are incandescent. Not only was the fact that gas is a bad conductor of heat against this view, but to prove its truth would necessitate that the blue part of the flame should be hot.

It cannot be said, as Mr. Foulis has remarked, that in no case is luminosity due to the presence of incandescent solid particles in flames; but on the other hand the theory of solid particles palpably fails to embrace many of the most striking facts connected with this subject. On the whole, the balance of evidence, as far as ascertained, is decidedly against that being generally adopted, and is in favour of the theory advanced by Prof. Frankland, who has shown that the luminosity of flames is much more likely to be due to the temperature of the flames, and to the relative densities of the vapours produced by the chemical combination of their constituents in the flame.

Obituaries.

MICHEL-EUGÈNE CHEVREUL.

FRANCE has in Chevreul lost, as a contemporary well remarks, "certainly the oldest of her grand men, if not the grandest of her old men." He died on Tuesday morning, April 9th, aged 102 years, seven months, and ten days.

On the previous Wednesday he took his daily ride to the Eiffel Tower, and observed, with almost childish glee, the flag on the top announcing the completion of the work. On his return home, faintness supervened, and medical aid was summoned. He lingered a few days, and at 1 a.m. on Tuesday peacefully expired, surrounded by his grandchildren and great-grandchildren. During the 48 hours preceding his death the aged chemist appeared unconscious and scarcely spoke. On Tuesday morning he opened his eyes and asked faintly, "*Où allons nous?*" These suggestive words were the last uttered by the famous Chevreul.

His principal scientific works may be enumerated as follows, and a glance at them will indicate their immense importance to Chemical Industry:—

- "Analysis of Guatemala Indigo," 1807.
- "Wood, Logwood, Nitrous Derivatives of Indigo, &c.," 1808—1813.
- "The Chemical Composition of Fatty Substances, their Decomposition into Glycerin and Fatty Acids, Saponification, &c.," 1813—1818.
- "On Animal Tissues, Fibrin, Albumin, &c.," 1821.
- "Stearates, Oleates, Phocenes, Butyrates, Caproates, and the corresponding Acids; Cholesterolin, Ethal, Stearin, Olein, Butyrin, Noieine, &c.," 1823.
- "The Influence of a Successive Look at two Different Colours," 1830.
- "Chemistry applied to the Art of Dyeing," 1830—1836.
- "Prussian Blue and its Changes on Printed Muslins," 1837.
- "On Gastric Juice," 1850.
- "Definition and Name of Colours, after a new Rational and Experimental Method," 1851.
- Many articles on Agricultural Chemistry, Dyeing, and Chemical Analysis, also published from 1851—1888.

The last paper read by M. Chevreul before the Academy of Sciences was on May 22nd, 1888, and was entitled "The Part played by Nitrogen in Vegetable Economy." It is said that Linnaeus died in the same house of the Jardin des Plantes, where Chevreul lived so long and breathed his last.

DR. WARREN DE LA RUE, F.R.S.

A MEMBER OF THE SOCIETY OF CHEMICAL INDUSTRY.

It is with regret that we have to announce the death of Dr. Warren de la Rue, which took place at his residence in Portland Place, N.W., on Friday evening, April 19th, at the age of 71 years. He was a native of Guernsey, was educated at the college of St. Barbe, Paris, and subsequently became senior partner in the firm of Messrs. Thomas de la Rue and Co. About the end of the year 1886 he retired from business.

In many branches of scientific inquiry he gained great distinction. The chief scientific work with which his name is associated is that of the application of photography to the recording of celestial phenomena. The photographs, when measured by a micrometer arrangement, which he invented, furnished exact astronomical data. In 1860 he was successful in obtaining a series of photographs of the total solar eclipse of July 18th. The results formed the subject of the Bakerian lecture delivered to the Royal Society in April 1862. In conjunction with the late Professor Balfour Stewart and Mr. B. Lowry, he published "Researches in Solar Physics," founded on observations made at the Kew Observatory under his direction. In 1874 he fitted up a private physical laboratory, where, employing a battery of 15,000 chloride of silver cells, he, in conjunction with his friend Dr. Hugo Müller, carried on a series of researches on the electrical discharge, the results being communicated to the Royal Society and the Académie des Sciences, Paris. Dr. de la Rue was a member of the International Electrical Congress and of the jury of the Electrical Exhibition held in Paris in 1881. He acted for some time as honorary secretary of the Royal Astronomical Society, of which he was also president from 1864 to 1866. He became President of the Chemical Society in 1867 and again in 1879, and was for many years President of the London Institution, from which he retired and became Secretary of the Royal Institution in 1878 on the retirement of Mr. Spottiswoode.

Dr. de la Rue was a corresponding member of the French Académie des Sciences for the department of Astronomy, of the Imperial Academy of Sciences, St. Petersburg, and of other foreign societies.

Three foreign orders were conferred upon him:—Commander of the Legion of Honour, Commander of the Order of St. Maurice and St. Lazare, and Knight of the Order of the Rose, Brazil.—W. S.

Journal and Patent* Literature.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Improvements in the Production of Cold and Manufacture of Ice, and in Machinery therefor. A. Conacher and O. L. Williams, London. Eng. Pat. 860, January 19, 1888. 1s. 1d.

The inventors propose various improvements in the apparatus used for producing ice by the vacuum process.

Instead of admitting into the freezing chamber a full body of water to be frozen all at one time, they allow small quantities of water only to enter intermittently and regularly by means of an automatic attachment, whereby the freezing is secured to take place from below, upwards, and a dense, clear, and transparent ice obtained. Several devices for the periodical admission of the water are described and shown in the drawings. The inventors aid the rapid and thorough absorption by the acid of the watery vapour by causing both acid and vapour to permeate a body composed of pumice stone, broken crockeryware, &c., which is porous and not affected by the acid.

They make use of an acid vessel or absorber constructed of iron, of such a shape as will lend itself to being readily lined or coated inside with enamel or glass, which enables the application of stronger acid, as well as the retention of the charge for a greater length of time before re-concentration is required. Nor need re-concentration be carried out under a vacuum, but it can proceed with free access to the atmosphere, as the enamelled iron vessel will safely withstand the greater heat necessary and the greater changes of temperature experienced under the latter circumstances.

They further provide suitable arrangements for mixing and agitation, in order to keep the acid in all parts of the absorber in proper condition. When using a body of pumice-stone, as before mentioned, in connexion with the enamelled absorber, the vacuum pump, and other appliances covered by the patent, it is found that the ice production can be continued even when the acid has attained to a very high temperature, such for instance as 77° C., a result which enables a larger amount of work to be achieved with a given apparatus in a stated time than could be done without the pumice-stone vapour-trap. The specification is accompanied with five sheets of drawings.—B.

Improvements in Apparatus for Compressing and Expanding Air or Gases, especially adapted for Refrigerating Purposes. F. Windhausen, Berlin. Eng. Pat. 2549, February 21, 1888. 11d.

THIS is a modification of part of an apparatus described in the Eng. Pat. 2864 of 1886 (this Journal, 1886, 133), and relates principally to an expansion cylinder provided between the condenser and refrigerator which the liquid carbonic acid enters and becomes cooled therein by partial vaporisation. The compressor is constructed on the principle of the "piston and plunger" pump, the annular space around the plunger being in open connexion with a second cylinder and filled with liquid which alternately enters and retreats from the second cylinder. The compressed gas reaches the expansion cylinder through a valve which is automatically closed at a certain early part of the stroke of the piston working in that cylinder, by which means the acid which has entered above the piston, expands, evaporates, and becomes cooled, until its pressure is about equal to that

* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Luck, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.	½d.
Above 8d., and not exceeding 18. 6d.	1d.
" 18. 6d., " " 28. 1d.	1½d.
" 28. 1d., " " 38. 1d.	2d.

in the refrigerator into which it is discharged. The drawings show several modifications of the compressing pump, glands, and valves.—B.

Improvements in Vessels, Apparatus, and Appliances for separating Solid Matter from Water or other Liquids during the Process of Purifying or Softening the same by Treatment with Chemical or other Reagents. T. L. Seaton, Padstow. Eng. Pat. 4547, March 21, 1888. 8d.

In place of the zig-zag or sloping shelves in the various forms of apparatus now in use for separating the precipitated matter from a water which has been softened or purified by the addition of reagents, the patentee proposes to use a chamber filled with balls made from any suitable material. A large surface for the deposit of the solid matter is thus secured.—C. C. H.

Improvements in Filter Presses. S. H. Johnson and C. C. Hutchinson, London. Eng. Pat. 4766, March 28, 1888. 8d.

The object of the patentees is to so construct a filter press that the chambers fulfil their functions without the use

of a textile fabric, mat, or media of a perishable description. Two general descriptions are illustrated in the specification:—(1.) Filter-press chambers are constructed in such a way that fine filtering silt is obtained on the filtering faces by the simple contact or juxtaposition of parts of which they are built up. The specification shows four different examples of this method. (2.) Filter-press chambers constructed in such a way as to secure a number of pockets, shelves, or receptacles which are filled with sand, or comminuted or porous material suitable for the purpose intended, through which the liquid filters. The bottoms of such receptacles are in communication with suitably formed outlets. Three examples of this method of construction are illustrated.

—C. C. H.

Improvements in Apparatus for the Evaporation and Condensation of Sea or Impure Water. O. M. Row, Walton, near Liverpool. Eng. Pat. 4775, March 29, 1888. 8d.

The object of this invention is to obtain fresh water from sea or other impure water by evaporation and condensation with the least loss of useful heat. The inventor describes its action in connexion with the accompanying illustration as follows, viz.:—

1 is an evaporator, 2 a condenser, 3, 4, 5, and 6 are pumps, 9 is a tank for condensed water, 34 and 39 are valve boxes one behind the other, regulated by floats in cistern 38; 54 is an auxiliary condenser.

Steam from a small boiler enters the engine 7 by pipe 52, and sets the pumps in motion, the exhaust steam passing by pipe 53 through the condenser 54 to the same boiler or to any other place as required. Steam from the boiler also enters space 10 through pipe 11, where it becomes condensed and flows into the tank 9. From here the condensed water is drawn through pipe 48 by pump 3 and forced through 49 back to the boiler, or is otherwise disposed of. Sea water or impure water is drawn by pump 4 through pipe 22 and is delivered through pipe 23 into the condenser 2, where it condenses the steam from the evaporator 1, and thence through the chamber 54, where it condenses the steam from engine 7. Part of the impure water flows away by the pipe 24, and part passes by the pipe 25 to the chamber 26 past a valve by the pipe 31 through the chamber 32 (where it is heated) into the evaporator 1. The salt or impure water in 1 is heated by steam in annular spaces within, and all steam liberated therefrom passes by pipe 45 into the chamber top 18, and thence through 2 condensed into 21. From 21 the pure water flows by pipe 46 to the pump 6, from which it is delivered by pipe 47 into chamber 38. A partial vacuum is also maintained in the condenser by pump 6, whilst the water in tank 38 will be at atmospheric pressure. A float in 38, by means of the lever 36, raises the valves in chambers 34 and 39, so that equal quantities of brine from the evaporator 1 and of the condensed water from tank 38 flow through the pipes 41 and 43. The brine reaches the chamber 32, where it heats the impure water; the fresh water passes to the tank 42, whence it is raised by the pump 5 to any desired place.—B.

Improvements in Apparatus for Accelerating the Passage of Liquids through Filter Beds. W. D. Bohm, London. Eng. Pat. 4824, March 29, 1888. 8d.

E is a filter bed of the usual construction; A is a single-acting pump in connexion therewith through suction pipe D; F is an auxiliary pump cylinder without suction or

delivery valves, but whose piston rod is connected with the tappet rod M, which through the connecting rod Q and hinged levers P P, opens and closes the cock K. After the pump A has drawn a quantity of the liquid through the material on the filter and discharged the same through the valve C, the pump F on the downward stroke closes the cock K and returns the charge through the filter bed, freeing its pores from the slimy matter which would otherwise remain upon and clog it.—C. C. H.

Improvements in Apparatus for Purifying Water for Boilers and other Steam Generators. G. W. Allen, Manchester, and H. J. A. Bowers, London. Eng. Pat. 5223, April 9, 1888. 8d.

THE improvements herein described consist—(1) in providing an injector, or its equivalent, to work in conjunction with the apparatus described in Eng. Pat. 7772 of 1887 (this Journal, 1888, 313), in order to secure good circulation; (2), the scroll separator illustrated in the present specification for the purpose of throwing oil, light scum, &c., from the surface of the water with which the boiler is being fed.—C. C. H.

Improvements in Apparatus for Condensing, Cooling, and Heating Fluids, and Machinery employed in the Construction thereof. J. H. Breze, Liverpool. Eng. Pat. 5246, April 9, 1888. 8d.

THIS invention deals with the use of flattened tubes bent into spiral or other form for the purpose of surface condensation, and includes the construction of tools for the production of tubes of the desired shape without first filling them with any pliable ductile material.—B.

Improvements in Means or Apparatus for the Production of Cold by the Expansion of Compressed Air. A. Marcet, London, and O. J. Ellis, Blackheath. Eng. Pat. 5274, April 9, 1888. 11d.

THE inventors describe apparatus in which compressed air supplied from any existing system of distributing mains is utilised both for providing motive power and for producing cold by expansion, whilst higher pressures may be brought about by the introduction of additional compressing cylinders. In these cylinders it is proposed to use suction and delivery valves of special construction, of which the two accompanying cuts show illustrations.

(For illustrations see top of page 272.)

The valves are annular in shape, double-edged, seated on annular openings and held down to their places by flat circular springs cut out radially like the spokes of wheels, between which spokes the air can escape. In the illustrations, K K are the valves, and m m the springs, the mode of fastening being also indicated.—B.

Improvements in and in connexion with the Method of and Apparatus for Cooling or Condensing Vapours. W. Schmidt, Halberstadt, Germany. Eng. Pat. 5418, April 12, 1888. 11d.

THE inventor's system of cooling and condensing may be gleaned from the claims appended to the specification, which are substantially as follows, viz. :—

1. The method of producing cold or of condensing vapours by allowing a current of heated gas to come into contact with an evaporative fluid and to get loaded with vapour at the expense largely of heat extracted from the fluid itself. The vaporous current of gas being subsequently deprived of the acquired moisture, is heated again and the process of taking up vapour repeated in a continuous cycle.

2. The method of producing cold or of condensing vapours from an evaporative fluid as described, and of using the said fluid as a cooling or condensing medium, at the same time that an independent evaporative fluid is employed for condensing the vapours contained in the heated current of gas. The movements of the fluids and gases form separate complete cycles.

The specification is accompanied by four sheets of drawings showing different arrangements and combinations of the apparatus.—B.

Fig. 1.

Fig. 2.

Improvements in Apparatus for Separating Liquids from Solid Matters in Suspension therein. J. S. Sawrey and H. Collett, London. Eng. Pat. 5426, April 12, 1888. *Sd.*

THE patentees describe a form of subsidence apparatus consisting, as is usual, of a vessel filled with sloping shelves. Such shelves, however, are so arranged that the liquid flows in a horizontal direction, passing into the spaces between the shelves at alternate sides; in this way a greater amount of settlement or subsidence is the result as compared with the form of apparatus in which the current flows alternately up and down between every alternate pair of shelves.—C. C. H.

Improvements in Apparatus for the Manufacture of Gas. A. McDougall, Penrith. Eng. Pat. 3495, March 7, 1888. *Sd.*

THE object of these improvements is to make the process of gas-making continuous. The coal is taken from a charging hopper by means of an Archimedeian screw and precipitated into the retorts. If these latter be horizontal, some mechanical device must be employed to promote the passage of the coal through them, but when they are vertical no such necessity exists. The tube containing the feeding screw is closed at the bottom by a seal of liquid in the charging hopper, tar being preferably employed for this purpose. A liquid seal also closes the receptacle into which the coke falls on leaving the retorts.—A. R. D.

II.—FUEL, GAS, AND LIGHT.

PATENTS.

Improvements in Treating Small Anthracite Coal and Rendering the same conveniently Available for Use as Fuel. J. T. Williams, Swansea. Eng. Pat. 1195, January 26, 1888. *Ad.*

THE dried small coal is mixed in a pug mill with blue clay, fire clay, shale, or Aberthaw lime, and then made under pressure into bricks. To protect these from atmospheric influence they are coated with pitch, tar, or other suitable substance. The following proportions are recommended for the mixing above mentioned:—Small coal, $14\frac{1}{2}$ cwt.; clay, 5 cwt.; and cement or lime, $\frac{1}{2}$ cwt.—A. R. D.

Improvements in Incandescence Gas Burners. C. von Buch, London. Eng. Pat. 2991, February 28, 1888. *Gd.*

THESE improvements constitute a new method for preparing incandescence mantles, by forming them from a skeleton of platinum electrically deposited. A "core" mantle of fine muslin is dipped in a solution of asphaltum and phosphorus in bisulphide of carbon, and then immersed for a few moments in a weak bath of silver nitrate, by which means it receives a covering of finely-divided silver. Over this a film of copper is electrically deposited, followed by a similar application of platinum or some other very refractory metal. After ignition and immersion in dilute nitric acid the platinum skeleton only is left behind. An alternative method of production is to deposit the platinum directly upon the carbonised "core" mantle.—A. R. D.

Improvements in or connected with Apparatus for the Carburation of Gas or Air. G. Seagrave and P. A. Olivier, London. Eng. Pat. 3538, March 7, 1888. *Sd.*

THE carburetted apparatus consists of an outer closed vessel (or hydrocarbon container) and an inner buoyant vessel through which the air or gas passes. This latter vessel, which is closed at the top and sides, is caused to float at a constant depth in the hydrocarbon in the outer vessel, and is provided with baffle plates to cause the gaseous current to take a zig-zag course. These baffle plates are clothed with flannel or other porous material dipping into the hydrocarbon below, and the zig-zag passages are hung with loose thread curtains to cause a more minute division of the gas. The means for introducing this latter into, and conveying it from the apparatus, are included in the improvements, and may be best understood by reference to the drawings attached to the specification.—A. R. D.

Improvements in Apparatus for Generating and Burning Gaseous Fuel. R. B. Avery, New York, U.S.A. Eng. Pat. 4158, March 17, 1888. *Sd.*

WITHIN a closed fire-box is placed a number of generating tubes which constitute the retorts. A steam injector drives oil into these tubes, and a portion of the gas here generated is mixed in a special mixing chamber with the requisite quantities of air, and consumed in the fire-box, thus heating the retorts. For details the specification and drawings must be consulted.—A. R. D.

Improvements in or connected with the Manufacture of Gas from Coal. J. H. R. Dinsmore, Liverpool. Eng. Pat. 4885, March 31, 1888. *Sd.*

COAL is distilled in retorts of any suitable kind, and the gas thus made conducted through heated passages (see

Eng. Pat. 15,852, of 1887; this Journal, 1888, 741) into which tar is also introduced. This addition has the effect of increasing both the quantity and the quality of the gas, the yield with Lancashire or Yorkshire coal running from 12,000 to 13,000 cubic feet of 21-candle gas per ton of coal. As this quality is higher than is required by most gas manufacturers, it is proposed to dilute it with hydrogen, water gas, or producer gas to, say, 17-candle power.—A. R. D.

Process for the Manufacture of Illuminating Gas and Coke. G. M. Westman, New York, U.S.A. Eng. Pat. 17,337, November 28, 1888. *8d.*

This invention consists in forcing superheated gas, made in the process, through a column of coal in a producer, and passing the gases leaving the producer through a shaft filled with glowing coke for the conversion of carbonic acid and moisture into combustible gas. The apparatus consists mainly of a producer, two regenerators or superheaters, and two coke shafts, provided with cooling arrangements and the necessary pipes and fittings. The regenerators, as also the coke shafts, are worked alternately, a blast of air being driven through each of the latter in turn to produce carbonic oxide, which is burned in one of the regenerators, while the other regenerator is superheating the gas to be forced through the fuel in the producer, and the second coke shaft is being traversed by the gases leaving the said producer.

—A. R. D.

Improvements relating to Apparatus for the Production of Gas from Liquid Hydrocarbon and to Devices for the Utilisation of Gaseous Fuel. De Witte Stearns, Des Moines U.S.A. Eng. Pat. 17,562, December 1, 1888. *8d.*

This specification describes a process and apparatus for the production of gas by passing superheated steam and liquid hydrocarbon through heated retorts. Each retort consists of a number of pipes connected together, and arranged parallel to one another in pyramidal form. The gas produced in the central retort is utilised for supplying heat to the apparatus. It is mixed with air and steam and delivered into a chamber, the floor of which slopes upwards towards the back. This sloping floor produces an equal distribution of pressure throughout the chamber, so that the gas issues through holes in the tiled roof in uniform streams, and burns in the combustion chamber above, in which are placed the retorts and the steam superheater. In lieu of perforations the tiles forming the roof above mentioned may be provided with parallel slots, over which fit semi-cylindrical burner tips, made of refractory material, and pierced with transverse slots.—A. R. D.

An Improved Incandescent Gas Burner. W. Hooker and D. Murray, Sydney, New South Wales. Eng. Pat. 19,055, December 31, 1888. *6d.*

The burner is made from a thin sheet of platinum irregularly perforated with a large number of holes and moulded or shaped to any desired form. The rough indented or "grater-like" surface is preferably turned outwards, and the burner itself is placed in a downward position. It is not connected directly with the supply pipe, but is fastened by means of platinum wire to a short length of porcelain tube, which screws into the supply pipe. This arrangement is intended to prevent the fusing up of the pipe end. When the gas is lighted the platinum burner soon becomes incandescent and diffuses a brilliantly white, soft light.—A. R. D.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Residual Paraffin. E. von Boyen. Chem. Zeit. 13, 29—30 and 64.

TOWARDS the end of the distillation of mineral oil, in Saxony and Thuringia, a hydrocarbon is produced which, owing to its prejudicial effects on the paraffin manufacture, is of some interest. It is obtained as follows:—The still fluid residues of the various retorts are collected together in one retort and again distilled, the distillate which contains paraffin being again distilled after acidulating and neutralising, and the distillate therefrom worked up for paraffin. On melting this crude paraffin a greenish-yellow precipitate separates, and this forms the raw material from which the new hydrocarbon is extracted. 13 kilos. of this were extracted twice with "solar oil" (a heavy petroleum naphtha) and the portion extracted crystallised out. The residue, after pressing, was dirty dark green in colour. From the first extract, and also from this residue, after extraction with warm "solar oil," only about 3 grms. of the new substance were obtained. A better result was attained by subjecting the product to distillation, when 40 per cent. of distillate passed over.

When determining the solidifying point of this distillate, according to Halle's method, a solid skeleton-like substance was observed in the melted globule of paraffin, and this fact formed the basis for a method of quantitatively separating this substance from the paraffin in its manufacture. The crude paraffin was heated to 70° in a dish, and the melted paraffin poured off and filtered, the residue consisting of a greenish-yellow substance, which, after repeated crystallisation from "solar oil" and benzene, melted at 317°, and possessed a pure yellow colour. It proved on further examination to be identical with Burg's *picene*.

It is almost insoluble in alcohol and ether and in most solvents; in "solar oil" and "photogen," boiling benzene, phenol, and the high-boiling oils, it is somewhat more soluble.

100 parts of paraffin, melting point 55°, dissolve only 0.84 parts of *picene* at 65°, while at high temperatures the two substances mix in all proportions. The latter crystallises in yellow plates with a strong green fluorescence. It colours substances with which it is mixed extremely yellow, 0.8 per cent. in paraffin giving a bright canary-yellow colour to the latter. This colour is, however, not possessed by the pure *picene*, as obtained by Burg, whose specimen was colourless and of a blue fluorescence. *Picene* boils at a temperature at which soft glass begins to become pliable. It sublimes, well, however, yellow plates a centimetre long being thus obtained.

Most reagents are without action on *picene*; it dissolves in concentrated sulphuric acid, at 100°, to a green solution, and in fuming sulphuric acid to a brown solution, not precipitated by water. A sulphonic acid was not obtained.

Chromic acid oxidises it to *picene-quinone*, as obtained by Burg, which is more soluble than *picene*, melts at 150° with decomposition, and dissolves in cold concentrated sulphuric acid with a dark violet colour, from which solution water precipitates some of the unchanged substance. It dissolves in phenol with a blood-red colour.

Subjected to the action of light and the atmospheric oxygen, *picene* is changed into the bright red *quinone*.

After making close observations the author was led to conclude that *picene* is formed towards the end of the paraffin distillation, in amount varying up to 5 per cent. After making a number of experiments the *picene* has been successfully separated from the residual paraffin, first by melting and filtration, which produces a paraffin of a bright yellow colour, and then by treating this with fuming sulphuric acid.—J. W. L.

Metacetone. E. Fischer and W. J. Laycock. Ber. 22, 101—105.

FREMY obtained by distilling sugar with lime a substance to which he gave the name metacetone, and the formula $C_6H_{10}O$. The authors find that this body is in reality a mixture of propylaldehyde, dimethylfurfuran, a third substance with hydrocarbon properties, and a number of other lower and higher boiling homologues. The authors distilled 100 kilos. of sugar and 300 kilos. of burnt lime and collected the distillate in fractions. Fraction A, distilling below 65° , combined partly with phenylhydrazine, and this consisted of the hydrazone of propylaldehyde. The distillate from this, and boiling at 25° — 45° , consisted of furfuran, and that boiling at 45° — 65° is probably methylfurfuran. Fraction B, distilling at 65° — 115° , was treated like fraction A, phenylhydrazine being added and the product distilled. The distillate consisted of a hydrocarbon and a substance, which dissolved on heating with dilute hydrochloric acid to 170° forming acetylacetone, and which is probably dimethylfurfuran. The residue, which combined with phenylhydrazine, is the hydrazone of propylaldehyde. The fraction boiling above 115° is a complex mixture consisting of higher homologues of furfuran and aldehydes, which could be removed with sodium bisulphite.

The authors have investigated wood tar and found that this likewise contains propylaldehyde and dimethylfurfuran. —J. B. C.

Chrysene hydrides. C. Liebermann and L. Spiegel. Ber. 22, 135—137.

On treating 1 part of chrysene with 1 part of red phosphorus and 5 parts of hydriodic acid (sp. gr. 1.7) at a temperature of 250° — 260° for 16 hours, the hydride is produced in the form of a crystalline compound melting at 115° and of the formula $C_{18}H_{30}$. Another non-crystalline product is also obtained, boiling at 360° , and having the formula $C_{18}H_{28}$. These bodies are exceedingly stable, resembling the paraffins in this respect. Bromine has no action, and fuming nitric acid produces no effect in the cold. The original chrysene cannot be regained either by oxidation with chromic acid or by distillation over red-hot pumice. —J. B. C.

Creolin. T. Weyl. Ber. 22, 138—139.

Two creolins are found in commerce—Artmann's and Pearson's. The author finds that the two preparations are distinct.

The following is the analysis of the two preparations :—

	Artmann.	Pearson.
Hydrocarbons	84.9	56.9
Phenols	3.4	22.6
Acids	1.5	0.4
Sodium	0.8	2.4

Both preparations contain coal-tar products boiling at 210° — 380° . The phenols are present as sodium salts.

—J. B. C.

IV.—COLOURING MATTERS AND DYES.

On Para-xylidine, its Preparation and its Properties. O. X. Witt, E. Noetting, and S. Forel. Bull. Soc. Ind. Mulhouse, 1888, 630—636.

COMMERCIAL xylidine contains 25 per cent. of para-xylidine. To prepare it the former is converted into its sulphonic compound by means of fuming sulphuric acid, containing 15 to 20 per cent. of anhydrous sulphuric acid. One

molecule of anhydrous sulphuric acid is used for one molecule of xylidine. The mixture is heated for some time on the water-bath and then poured upon ice. The sulphonic acid of meta-xylidine is with difficulty soluble in dilute sulphuric acid, and crystallises out. The mother-liquor contains para-xylidine sulphonic acid. This is converted by chalk into the lime salt, and its solution after conversion into the sodium salt evaporated until crystallisation sets in. The sodium salt is with difficulty soluble in cold water.

On distillation with dry ammonium chloride para-xylidine is obtained. The sodium salt of meta-xylidine sulphonic acid chars under the same treatment. Para-xylidine boils at 212.5° C. Its specific gravity is 0.98. The efforts to prepare the hydrocarbon did not prove successful. The phenol was always formed on treatment of the base with ethyl nitrite and sulphuric acid in absolute alcohol.

Xylenol crystallises out from water in long needles melting at 74.5° C., and boiling at 210° C. Its ethyl ether is a liquid boiling at 205° C. To prepare the hydrocarbon the authors converted the pure diazoxylene into iodoxyline by means of hydriodic acid and then reduced the iodine compound by sodium amalgam. The hydrocarbon thus obtained was oxidised and terephthalic acid obtained. Acetyl para-xylidine melts at 139° C. On nitration, nitro-acetyl-p-xylidine is obtained, crystallising from water in long needles melting at 166° C., which on saponification yields a nitro-xylidine melting at 142° C. On reduction of the latter, p-xylene diamine is obtained, crystallising from benzene in small white needles melting at 146.5° to 147° C. This diamine, as well as the p-xylidine, produce on oxidation with potassium bichromate and sulphuric acid p-xyloquinone (phlorone) crystallising from benzene in long yellow needles melting at 123° C. It is but slightly soluble in water and volatile with steam. The corresponding quinol crystallises from water in small white plates, which sublime and melt at 210° C. On treating nitro-para-xylidine with ethyl nitrite and ethyl alcohol the ethyl ether of p-xylidine was obtained instead of the nitrohydrocarbon. Several commercial xylidines were examined and all proved to contain at least 25 per cent. of para-xylidine. —A. L.

The Sulphonic Acids of Meta- and Para-Xylidine. E. Noetting and O. Kohn. Bull. Soc. Ind. Mulh. 1888, 636—647.

Meta-xylidinesulphonic Acid—

is always obtained, whatever the conditions of the sulphonation may be. It is with difficulty soluble in hot or cold water, and may be purified by crystallisation from it. It forms long flat white prisms. It chars on heating, forming only traces of xylidine. Hydrochloric acid decomposes it at 180° C. into xylidine and sulphuric acid. The barium salt is easily soluble in water, and retains two molecules of water of crystallisation which are given off only at 140° C. The xylidinesulphonic acid obtained from nitro-meta-xylene-sulphonic acid is identical with the one above described.

Diazo-meta-xylenesulphonic Acid.—White plates, decomposing at 60° — 70° C., and forming colouring matters with phenols and amines.

Bromoxylenesulphonic Acid is obtained from the former body by treating it with concentrated hydrobromic acid. Its barium salt crystallises with one molecule of water. The sodium salt being treated with phosphorus pentachloride, and afterwards with ammonia, is converted into the sulphonic amide, crystallising from alcohol in small rhombic prisms, melting at 189° — 190° C. When this compound is reduced in warm alcoholic solution with sodium amalgam xylenesulphonic acid, $C_6H_4CH_3(CH_3)SO_3H [1:3:4]$ is obtained; the bromo-acid is therefore identical with the one described by Weinberg.

Bromoxylidinesulphonic Acid is obtained by adding to the alkaline solution of xylenesulphonic acid one molecule of bromine dissolved in caustic alkali, and by acidulating afterwards. Small white needles soluble in boiling water.

Paraxyldinesulphonic Acid—

Its barium salt crystallises with 7 mols. of water and is easily soluble in water.

Diazoparaxylenesulphonic Acid prepared in the usual way forms brilliant yellow needles decomposing with water at about 60–70 °C. It combines with phenols and amines, and is converted by hydrobromic acid into *Bromoparaxylenesulphonic acid*. The barium salt crystallises with 2 mols. of water. Its chloride, $\text{C}_6\text{H}_2(\text{CH}_3)_2\text{Br}(\text{SO}_3\text{Cl})$ crystallises from benzene in small prisms melting at 77–78 °C. Its amide, $\text{C}_6\text{H}_2(\text{CH}_3)_2\text{Br}(\text{SO}_3\text{NH}_2)$ forms small white crystals melting at 200–201 °C., easily soluble in alcohol and ether, difficultly in boiling water, benzene, and chloroform. The authors did not succeed in preparing a bromoparaxyldinesulphonic acid. The sulphonic acid group was always eliminated and dibromoparaxyldine obtained, melting at 65 °C., and crystallising from petroleum spirit in white needles. On oxidation of paraxyldine with chromic acid paraxyloquinone is formed, which proves that the sulphonic acid group is in para position to the amido group.

Paraxyldinesulphonic Acid—

prepared by heating one part of paraxylenesulphonic acid with $\frac{2}{3}$ parts of nitric acid for several hours on the water-bath. The nitro-compound was reduced; the amido-compound is very little soluble in cold water, crystallises from hot water in white needles with one molecule of water. On oxidation no paraxyloquinone is formed. On treating its alkaline solution with one molecule of bromine in alkaline solution and on acidulating afterwards, *Bromoparaxyldinesulphonic acid* is formed, nearly insoluble in cold water.

—A. L.

The Sulphonation of Primary, Secondary, and Tertiary Rosaniline Bases. O. Mühlhäuser. *Dingl. Polyt. J.* **271**, 359–363.

GENERALLY rosaniline bases containing NH_2 groups are sulphonated with difficulty, as are also N-alkyl rosanilines.

On the other hand, phenyl and benzyl rosanilines of secondary and tertiary, or mixed secondary and tertiary nature, are easily sulphonated. From this the conclusion has been drawn that substitution takes place in these benzyl and phenyl groups.

The following means of sulphonation have been suggested:

- (1.) H_2SO_4 .
 - (a.) Pure, at 66° B. (Nicholson).
 - (b.) As monohydrate in the form of strong sulphuric acid, mixed with glacial metaphosphoric acid (2:1) (Kalle & Co.).
 - (c.) Combined with rosaniline as bisulphate (Kalle & Co.).
- (2.) SO_3 .
 - (a.) Pure SO_3 (H. Caro).
 - (b.) Mixed with H_2SO_4 (Monnet and Dury, and H. Caro).
 - (c.) As a mixture of H_2SO_4 and $\text{Na}_2\text{S}_2\text{O}_7$ (Meister, Lucius, and Brüning).
 - (d.) As ethionic anhydride, $\text{C}_2\text{H}_4\text{SO}_3$ (F. Mann).
- (3.) SO_3HCl .
 - (a.) As pure sulphuric chlorhydrin (Jacobsen).
 - (b.) As ethionic chlorhydrin (Mann).

The action of these substances on rosanilines,—for instance, on triphenyl-pararosaniline—is shown in the following equations:—

Then follows an historical account of the subject, and some general remarks as to practical details. The duration of the action and the temperature to be employed depend upon the nature of the sulphonating agent. Sulphuric anhydride acts quickly, and does not require the aid of external heat. Fuming sulphuric acid, and especially ordinary sulphuric acid, act slower, and must be aided by external heat. Strong sulphuric acid is suitable for the sulphonation of secondary or tertiary rosaniline bases, containing phenyl or benzyl groups. Primary rosaniline bases and their fatty alkyl-derivatives require the use of fuming acid or sulphuric anhydride. The separation of the sulphonic acids from the excess of sulphuric acid may be accomplished in two ways. When the sulphonic acids are insoluble in water, the mixture is simply largely diluted and filtered. In cases where the sulphonic acids and their calcium salts are soluble, the mixture is neutralised with milk of lime and filtered. The free acid can be prepared from the calcium salt thus obtained.—H. T. P.

Nitration. L. Meyer. *Ber.* **22**, 18–23.

THE nitration of benzene, like many reactions, proceeds rapidly at first, but gradually slackens as the amount of nitro-compound increases. The process of nitration is, however, so far different to other reactions, that nitric acid appears to increase and benzene to hinder the process, whether the latter is in excess or not. Thus 100 parts of nitric acid give, with 100 parts of benzene, 17 parts of nitrobenzene in 15 minutes; but only 3.6 parts if 700 parts of benzene be used with the same quantity of acid. With a given quantity of nitric acid, the less benzene present the greater the quantity of nitrobenzene is formed in the first stage of the reaction. If 100 equivalents of benzene (mixed with 100 equivalents of nitrobenzene to prevent oxidation) be treated with varying quantities of nitric acid, the quantity of nitro-product varies proportionately with the amount of acid, at the rate of about 2.55 per cent. on every 50 equivalents of acid added. With an excess of acid the proportion increases because, firstly, the presence of nitric acids aids the nitration, and, secondly, a larger percentage nitrites.

The nitration at the beginning, therefore, varies as the square of the amount of acid present.

The subsequent slackening of the reaction is due to the formation of water, but as water cannot convert nitrobenzene into benzene and nitric acid, it is probably due to the diluting of the acid. Nitrobenzene prevents the action more than benzene or than its equivalent of water. The diluting action of water is difficult to follow experimentally, as the liquid divides into layers; but when pure HNO_3 is diluted with its equivalent of water, the action appears to stop. Two equivalents of pure acid, or an equivalent of acid and a corresponding quantity of sulphuric acid, are necessary to complete the action.—J. B. C.

The Action of Sulphur on the Toluidines. L. Gattermann. *Ber.* **22**, 422–426.

TWO compounds appear to be formed by the action of sulphur upon paratoluidine at a high temperature; the one is the subject of a German patent by the firm of Dahl and Co. and the other is the colouring matter known as “primuline” (this Journal, 1888, 180, 386, and 561). The principal difference is the insolubility of the basis of the latter substance in alcohol, and the strong affinity of its sodium sulphonic acid derivative for cotton fibre. If 100 grms. of toluidine and 60 grms. of sulphur be heated to 185° in an oil-bath, sulphuretted hydrogen is evolved. The product may be crystallised from acetic acid or dilute alcohol, and melts at 191°. This is Dahl’s thiotoluidine:—

Its alcoholic solution has a blue fluorescence. By the action of nitrous acid in alcoholic solution, a compound of the formula $\text{C}_{11}\text{H}_{11}\text{NS}$ is obtained in crystals, indicating the presence of one amido-group. It takes up bromine by addition.

The primitive substance of primuline may be crystallised from naphthalene as it is insoluble in the usual solvents. It has the formula $C_{14}H_{10}N_2S_2$, and is probably formed as follows:—

Orthotoluidine and sulphur also combine to form a thio base, which has a similar composition to that from the para-compound. It also yields an addition product with bromine of the formula $C_{11}H_{12}N_2S \cdot Br_2$ —J. B. C.

On the Isomeric Sulphonic Acids of Beta-naphthylamine.
A. G. Green. Ber. 22, 721—724.

It is known that on sulphonating β -naphthylamine by means of ordinary sulphuric acid, a mixture of α - and γ -acids is produced at low temperatures, and at higher temperatures (160° — 170°) a mixture of β and δ . According to the formulæ usually assumed for these acids, the first pair have their sulphonic groups in α -positions, the second pair in β -positions; and their formation is exactly analogous to that of the α - and β -sulphonic acids of naphthalene. According to Dahl (Ger. Pat. 32,276) the product at 100° consists of α -, β -, and γ -acids, but the author finds that, as was to be expected, the δ -acid is also present. The four acids can be readily isolated by a slight modification of Dahl's process. The ammonium salts of the four acids were found to differ in a very characteristic manner: that of the β -acid is less soluble than the three isomeric salts, and by means of this salt the β -acid was obtained in a pure state, and was found to crystallise in prismatic needles, and not as usually stated in naereous plates, the latter form being dependent on the presence of a trace of δ -acid. Although beta-naphthylamine gives four isomeric acids on sulphonation, only two sulphonic acids are supposed to be formed by sulphonating β -naphthol; but bearing in mind the analogous behaviour of hydroxy- and amido-compounds, it would appear much more probable that four acids are formed in the latter case also, and hence a search was made for the δ -sulphonic acid in the product of sulphonation of β -naphthol at 100° . As the separation of isomeric β -naphthol sulphonic acids presents great difficulties, the method adopted consisted in converting the sulphonation product into the corresponding β -naphthylamine sulphonic acids and separating these. By this means it was proved that the product formed at 100° is a mixture of the β - and δ -isomers. Hence at higher temperatures, at any rate, β -naphthol behaves on sulphonation like β -naphthylamine; whether this is also the case at low temperatures remains to be seen.

On Reduction Products from Azo Colouring Matters of the Naphthalene Series. O. N. Witt. Ber. 21, 3468—3489.

The author has examined reduction products obtained by reducing combinations of diazobenzene with different beta-naphthol and alpha-naphthylaminesulphonic acids. 1 gram. of the previously-purified substance was always taken, and as reducing agent, 2 gram. of tin crystals dissolved in 5 cc. of pure hydrochloric acid, sp. gr. 1.19, were used. The colouring matter was dissolved in the sufficient quantity of boiling water (10 parts of it is sufficient in most cases, in no case more than 20 were required). As soon as all is dissolved, the flask is removed from the fire, and the tin protochloride solution is added at once. The reduction takes place at once, the liquid frequently boiling violently. The amidonaphthol or naphthylenediaminesulphonic acid separates: either at once or after cooling, or not at all.

Beta-naphthol Derivatives.—Azo-colours obtained from beta-naphthol yield, on reduction, amido-beta-naphthol. When Mandarin or Beta-naphthol orange is reduced with the above-described tin protochloride solution, white crystals are obtained on cooling, which consist, after washing with dilute hydrochloric acid, alcohol, and ether, of amido-beta-naphthol hydrochloride, soluble in pure water. This solution is not precipitated by caustic alkali or ammonia, but turns brown. Acetate of soda, however, precipitates glittering plates of the free amido-naphthol, crystallising from ether in square plates. Ferric chloride produces in

the solution of the hydrochloride abundant quantities of beta-naphthoquinone. The sulphonic acid which is formed in the reduction process remains in the mother-liquor as hydrochloride.

Beta-naphthol-monosulphonic Acid Derivatives.—Of the seven isomeric betanaphtholmonosulphonic acids, four are known and used technically:—

(1.) The so-called Bayer's croceinesulphonic acid—

This formula is generally used to express the constitution of this body, but it is not free from objections, as will be shown hereafter.

(2.) Schäffer's beta-naphthol-beta-monosulphonic acid, the probable constitution of which is $C_{10}H_6(SO_3H)OH [3':2]$.

(3.) Casella's beta-naphtholmonosulphonic acid F, obtained by fusing alpha-naphthalenedisulphonic acid with caustic soda at 260° — 250° C., and identical with the one obtained by boiling Bayer's and Dnisberg's β -diazonaphthalene-delta-sulphonic acid with water, and which is expressed by $C_{10}H_6(SO_3H)OH [2:2']$.

(4.) Dahl's beta-naphthol- γ -sulphonic acid, obtained by boiling beta-diazonaphthalenemonosulphonic acid, which is believed by Reverdin and Noëling to have constitution—

All these acids are capable of producing colouring matters with diazo compounds.

Amido-beta-naphthol-alpha-sulphonic Acid was obtained in the above-described manner. It separates from the hot solution and is always red. Recrystallised from a hot sodium acetate solution, it possesses the formula $C_{10}H_7(OH)(NH_2)SO_3H$, soluble in alkalis, &c., but the solution turns rapidly a deep orange-brown when in contact with air. Oxidising agents produce the same effects in neutral or alkaline solution. Silver salts are reduced at once in acid or in ammonia solutions, the metal being separated in powder. Sodium nitrite acts on the acid, but does not form a diazo-compound. Diazo-compounds do not act on the acid, but are decomposed with evolution of nitrogen. Nitrosodimethylaniline hydrochloride heated together with this body in a solution of acetic acid of 50 per cent. produces a violet colouring matter, which in aqueous solution is changed into red by caustic soda.

Amido-beta-naphthol-beta-sulphonic Acid separates from the hot solution in white crystals. It is purified by mixing the acid with glacial acetic acid, boiling and adding so much of an aqueous solution of sodium acetate of 20 per cent. that all is dissolved. The solution is quickly filtered and hydrochloric or sulphuric acid added. The acid is precipitated and filtered from the hot solution. A product treated twice in such a way, washed with alcohol and ether, and dried at 110° C., proved pure. It is the same acid which Griess and Meldola have already mentioned.

If small quantities are dissolved in boiling water and the solution is cooled with ice, the acid is obtained in white needles. If, however, the solution is kept at ordinary temperature, the solution remains mostly clear, becomes yellow after some standing, and finally dark brown. Alkaline solutions show these changes of colour within a few moments. Larger quantities of this acid cannot be dissolved in water without decomposition. Brown solutions result, turning violet on addition of hydrochloric acid. Oxidising agents act on the acid in the same manner as on the alpha-compound. Nitrosodimethylaniline does not produce any colour. Diazo-compounds produce colouring matters when acting on this acid. Diazobenzene forms a red-like magenta and tetrazostilbenesulphonic acid a beautiful red-violet, which is turned into an insoluble blue by addition of hydrochloric acid. None of these colouring matters dyes wool.

Amido-beta naphthol-delta-sulphonic Acid resembles the beta-acid. Nitrosodimethylaniline does not produce a colouring matter. It combines with some diazo-compounds, but only very slowly. Brünner's beta-diazonaphthylamine-sulphonic acid produces only decomposition, whilst the beta-acid yields a beautiful red violet with it.

Amido-beta-naphthol-gamma-sulphonic Acid is soluble with great difficulty, and is the most stable of the four isomers; neither nitrosodimethylaniline nor diazo-compounds act on it.

Amido-beta-naphthol-alpha-disulphonic Acid crystallises from the cold solution in white needles. It is advisable to add to its solution an equal volume of saturated sodium chloride solution, to accelerate the precipitation of the acid. This body is stable when dry, but easily decomposed in solution. To prepare it entirely pure, 0.5 grm. were quickly dissolved in 5 cc. of acidulated water; the solution was mixed with the same volume of cold alcohol and the glass put into a freezing mixture. By repeating this mode of purification a body was obtained, the analysis of which proved it to be the acid sodium salt of the amidonaphtholdisulphonic acid. Alkalis quickly produce oxidation; neither diazo-compounds nor nitrosodimethylaniline form colouring matters. The decomposition of the aqueous solutions is very remarkable. After warming for a short time they contain the ammonia salt of a new acid, probably dihydroxynaphthalene-disulphonic acid.

Amido-beta-naphthol-gamma-Disulphonic Acid is obtained as calcium salt from its solutions after addition of calcium chloride in large dichroic crystals, easily soluble in hot, difficultly in cold water.

It is advisable to add sodium chloride to the solution after the reduction is completed to precipitate the acid sodium salt of amido-beta-naphtholdisulphonic acid. This acid is acted upon much more slowly by oxidising agents than the before described. Silver nitrate is also reduced, but only after a few minutes standing, whilst the alpha-compound is at once acted upon.

Reduction Products from the Colouring Matters of Beta-naphthylaminemonosulphonic Acid.—This acid is patented by the Badische Anilin und Soda Fabrik, and forms with diazobenzene salts a yellow colouring matter. This is, however, not an azo- but a diazo-amido compound. On reduction beta-naphthylaminemonosulphonic acid and phenylhydrazine are formed.

Orthonaphthylene-diamine-beta-monosulphonic Acid is obtained by reducing azo-colours containing Bronner's beta-naphthylaminemonosulphonic acid. It separates even from warm solutions, and is purified by solution in sodium acetate and reprecipitation with acids. Difficultly soluble in hot water, the alkaline solution turns brown through the influence of the air. Excess of sodium hydrate precipitates the sodium salt. Ferrieyanide of potassium turns the solution first brown, afterwards yellow. Ferric chloride produces a dirty green precipitate. Phenanthrenequinone dissolved in sodium bisulphite and added to a solution of the acid in sodium acetate acidulated with acetic acid, separates, when heated gradually on the water-bath, a mass of yellow needles of naphthophenanthrazine sodium monosulphonate. It is distinguished from its isomer by its red-violet solution in sulphuric acid, whilst the isomeric compound dissolves with a blue-violet colour in this agent. If fused with caustic potash an euhodol is obtained as a brown gelatinous precipitate after acidulating the melt, soluble in concentrated sulphuric acid with a pure ultramarine-blue colour; precipitated by addition of water it forms a cherry-red sulphate. The isomeric alpha-compound dissolves in sulphuric acid with an indigo-blue colour, and the sulphate is a brilliant carmine-red precipitate.

Orthonaphthylenediamine-delta-sulphonic Acid, obtained in a similar way as before described, is more soluble in water than the beta-compound. Alkalis, ferrieyanide of potassium, and ferric chloride act on it as on the beta-compound. Sodium hydrate, however, does not precipitate a sodium salt. It forms an azine compound like the body before described, soluble in concentrated sulphuric acid with a red-violet colour. The euhodol, however, dissolves in sulphuric acid with a pure violet colour, and on dilution a brownish-red sulphate is precipitated.

Orthonaphthylenediamine-gamma-monosulphonic Acid, light brown plates, with difficulty soluble in water, but more easily than the beta-compound. Ferric chloride produces in its aqueous solution a deep green colouration, from which, after some

standing, a dark green precipitate separates. Its azine derivative dissolves in sulphuric acid with a violet colour, turning orange on dilution. The corresponding euhodol solution in sulphuric acid is black-violet. On dilution the solution turns at first cherry-red and then a dirty-red sulphate is precipitated. The solution of the potassium euhodolate is orange-yellow.

Disulphonic acids of beta-naphthylamine.—Only two are known, obtained from the corresponding beta-naphtholdisulphonic acids. They are technically known as "Amido-acid R" and "Amido-acid G." The latter or gamma-acid is not capable of combining with diazo-compounds. The alpha-acid, however, produces colouring matters, which on reduction form colourless solutions. On addition of the same volume of hydrochloric acid and a little sodium chloride the acid sodium-salt of a naphthylenediaminedisulphonic acid is precipitated, easily soluble in boiling water. Calcium chloride precipitates an acid calcium salt. Alkalis and silver salts act on it as on the gamma-monosulphonic acid. Ferric chloride produces a deep green solution. By the azine reaction the sodium salt of naphthophenanthrazine disulphonic acid is obtained as a gelatinous mass, which could not be crystallised. The sulphuric acid reaction is very characteristic, a blue magenta-red turning on dilution first yellow, then orange. The euhodol dissolves in sulphuric acid with a green-blue colour, turning on dilution at first violet, then claret-red, finally separating the free euhodol as a yellowish brown precipitate. The monosulphonic acids always form the sulphate.—A. L.

On the Constitution of Beta-Naphthol-Alpha-Monosulphonic Acid. O. N. Witt. Ber. 21, 3189—3192.

ARMSTRONG has converted this acid into bromo-beta-naphthol, for which he considers the constitution—

as proved, and he believes the sulphonic acid to have the same constitution. Claus and Volz prepared a dichloronaphthalene of the same acid, melting at 61° C., which they believed to contain the chlorine atoms in the β_1 — β_2 position.

From the beta-naphthol-alpha-monosulphonic acid can be easily obtained an amido-compound, which, if Armstrong's formula be correct, would be—

and which after elimination of the sulphonic-group would yield an amido-beta-naphthol, β_1 — β_2 . This body ought to yield on oxidation, the third hitherto unknown naphthoquinone. When the amidonaphtholsulphonic acid was heated in sealed tubes for 4—5 hours with concentrated hydrochloric acid to 120° C., white crystals were formed, which were proved to be dihydroxynaphthalene. The sulphonic-group and the amido-group were eliminated. This body decomposed rapidly at the air and was therefore not further purified, but at once oxidised with ferric chloride. A quinone was obtained, identical in every respect with beta-naphthoquinone. It is therefore proved that the amido-group is in the alpha position, and that, therefore, Armstrong's formula is not the correct one for this beta-naphthol sulphonic acid.

—A. L.

New Prussian Blue. C. E. Guignet. Compt. Rend. 108, 178—181.

Ordinary Prussian Blue which has been purified by acids in the usual manner, may be readily converted into the soluble modification by boiling with potassium ferro-ferrieyanide. The latter is most conveniently prepared by gradually adding to a boiling solution of 110 grms. of potassium ferrieyanide a hot solution of 70 grms. of ferrous sulphate. Only one-half of the ferrieyanide enters into the reaction. The mixture is now boiled for two hours, filtered, and washed with pure water until the wash water assumes a deep blue shade. The residue is dried at 100°. This blue dissolves readily in water and is very suitable for anatomical injections, as it remains in solution in presence of considerable quantities of gelatin. From the filtrate a further quantity of soluble blue may be obtained by adding 55 grms. of ferrieyanide and 70 grms. of ferrous sulphate.

If necessary, the soluble blue is freed entirely from ferri-cyanide by washing with weak alcohol (40 per cent.). Solutions of soluble blue are precipitated by concentrated solutions of sulphate or chloride of sodium.

Pure Soluble Prussian Blue is prepared by digesting an excess of Prussian blue paste with a saturated solution of oxalic acid. The filtrate, after standing for two months, deposits the pure blue, the liquid itself becoming colourless. The colour is washed with weak alcohol and dried. It now dissolves readily in pure water. The same result is obtained more rapidly by precipitating the oxalic acid solution with 95 per cent. alcohol, or a concentrated solution of sulphate of soda, and washing the colour with weak alcohol. Tartrate or oxalate of ammonium can take the place of the oxalic acid in the above reactions. On boiling the oxalic acid solutions, ordinary insoluble blue is precipitated. Dilute sulphuric acid also precipitates the insoluble modification.

New Solvents of Prussian Blue.—By boiling Prussian blue with molybdic acid, a deep blue solution is obtained which is not precipitated by gelatin, but, on cooling, the solution sets to a transparent deep blue mass. Instead of molybdic acid, molybdate and tungstate of ammonium may be employed.

Action of Sulphuric Acid.—Prussian blue treated with concentrated sulphuric acid, forms a white paste which on heating is partially decomposed, giving off hydroferrocyanic acid. By treating dry powdered Prussian blue with a mixture of equal parts of sulphuric acid and alcohol for several days it dissolves. On addition of water ordinary Prussian blue is precipitated. The author considers that the soluble product is a sulphuric acid derivative.—A. R.

On Naphthylene Diamines. Zeits. f. angew. Chem. 1889, 48—49.

Ewer and Piek have observed that the dihydroxynaphthalenes when heated with ammonia form naphthylene diamines. For preparing α - α -naphthylendiamine, one part of α - α -dihydroxynaphthalene is heated for 8—10 hours with five parts of ammonia solution (saturated at 10° C.). On opening the vessel the naphthylene diamine is almost entirely crystallised from the ammoniacal solution. Nitrous acid converts it into a diazo-compound, capable of combining with phenols and amines. The following table shows the properties of the different naphthylene diamines.

Mode of preparation.	From α -nitro-naphthylamine by reduction, and from azo-compounds of α -naphthylamine.	From α -dinitro-naphthalene.	From β -dinitro-naphthalene.	By reducing azo-compounds of β -naphthylamine.	From $\alpha_1 - \alpha_3$ Dihydroxy-naphthalene.
Form of crystals.	Plates.	Needles.	Needles.	Plates.	Needles.
Melting point.	120° C.	189.5° C.	66.6° C.	95° C.	189° C.
Hydrochloride.	Plates.	Needles (?)	Plates.	Plates.
Sulphate.	Needles.	Plates.	Needles.
Reaction of the hydrochlorides with ferric chloride.	Green colouration.	Blue colouration, then blue precipitate.	Chestnut-brown precipitate.	Green, then yellow colouration, brown precipitate.	Blue colouration, then precipitate.
Action of nitrous acid.	Soluble tetrazo-compound.	Soluble tetrazo-compound.	Vermilion precipitate.	Soluble tetrazo-compound.
Action of the azo dyes-stuffs on unmordanted cotton.	Do not dye.	Dye the fibre.	Dye the fibre.

On the Preparation of a New Naphtholdisulphonic Acid. Zeits. f. angew. Chem. 1889, 49.

TWENTY kilos. of naphthalene are mixed with 100 kilos. of fuming sulphuric acid, containing 23 per cent. of anhydrous sulphuric acid. When the naphthalene is dissolved 14 kilos. of strong nitric acid are gradually added, the mixture being constantly stirred and well cooled with ice. After completion of the reaction the product is poured into one cubic metre of water made alkaline with lime, and after filtration from the calcium sulphate and partial evaporation, reduced with iron and sulphuric acid. Milk of lime is again added, the calcium salts are converted into the sodium salts, and the solution is evaporated until crystallisation sets in. On cooling the neutral sodium salt of the amidonaphthalenedisulphonic acid, described in Patent 40,571, crystallises. From the mother-liquor hydrochloric acid precipitates the acid sodium salt of a new naphthylaminedisulphonic acid. The free acid crystallises with 1 mol. of water. The conversion into an α -naphtholdisulphonic acid is done in the usual way through the diazo-compound. Its sodium salt crystallises in colourless prisms, containing 6 mols. of water [Schöllkopf's α -naphtholdisulphonic acid contains 1 mol. of water, and crystallises in small plates]. The new acid does

not yield a nitro-compound on treatment with nitric acid, but is oxidised. The α -naphtholdisulphonic acid, described in Patent 32,291, produces, on treatment with nitric acid, dinitronaphthol and dinitronaphtholsulphonic acid. The new α -naphtholdisulphonic acid is distinguished further from these isomerides by its colouring matters, obtained by conjugating with diazobenzene and diazonaphthalene. The following table shows these distinctions clearly:—
